

23.30. There is no loss of energy in the system. The initial potential energy of the system will be converted to their kinetic energy. Moreover the particles are at rest initially, that is they have zero momentum. Hence when they move apart they will have <sup>velocity</sup> ~~speed~~ in opposite direction of same magnitude.

$$\text{Initial electrostatic energy} = \frac{Q^2}{4\pi\epsilon_0 r} = \frac{Q^2}{4\pi\epsilon_0 r}$$

$$\text{Kinetic energy of two particles} = 2 \times \frac{1}{2} m v^2 = m v^2$$

$$m v^2 = \frac{Q^2}{4\pi\epsilon_0 r}$$

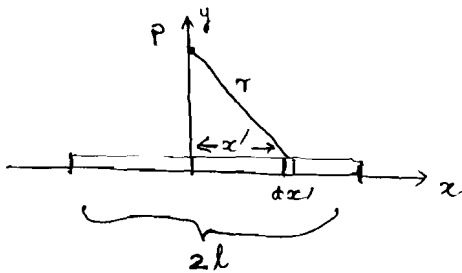

$$\therefore v = \sqrt{\frac{Q^2}{4\pi\epsilon_0 m r}} = \sqrt{\frac{(5.5 \times 10^{-6})^2 (8.99 \times 10^9 \text{ Nm}^2/\text{C}^2)}{(10^{-6} \text{ Kg}) (0.065 \text{ m})}} = 2 \times 10^3 \text{ m/s}$$

23.36. In this example the center where we are finding the potential is at equal distances (radius) from all points on the semicircle.

For a semicircle of radius  $r_0$ , its circumference is  $\pi r_0 = l$ .

$$V = \frac{1}{4\pi\epsilon_0} \int \frac{dq}{r} = \frac{1}{4\pi\epsilon_0 r_0} \int dq = \frac{Q}{4\pi\epsilon_0 r_0} = \frac{Q}{4\epsilon_0 l} \quad (\because r = r_0 \text{ for all})$$

23.38.

we choose a small length element  $dx'$  at a distance  $x'$  from center of rod and find the potential due to that. Total charge on rod =  $Q$ .  
 Charge on length  $dx' = \frac{Q}{2l} \cdot dx'$

Distance between the charge and the pt. P is  $r = \sqrt{x'^2 + y^2}$ .

$$\begin{aligned} \therefore V &= \frac{1}{4\pi\epsilon_0} \int \frac{dq}{r} = \frac{1}{4\pi\epsilon_0} \int_{-l}^l \frac{\frac{Q}{2l} dx'}{\sqrt{x'^2 + y^2}} \\ &= \frac{Q}{8\pi\epsilon_0 l} \left[ \ln(\sqrt{x'^2 + y^2} + x') \right]_{-l}^l = \frac{Q}{8\pi\epsilon_0 l} \ln\left(\frac{\sqrt{l^2 + y^2} + l}{\sqrt{l^2 + y^2} - l}\right) \end{aligned}$$

23.55. The gain in the kinetic energy comes from the loss in potential energy as there is no energy loss associated with the system. The helium atom has a charge  $2e$ .

$$\Delta K.E. = -\Delta U = -qV$$

$$\therefore V = -\frac{\Delta K.E.}{q} = -\frac{125 \times 10^3 \text{ eV}}{2e} = -62.5 \times 10^3 \text{ V}$$

23.58. The charge of the particle does not affect its kinetic energy and not needed here.

$$K.E. = \frac{1}{2} m v^2 \quad (v \text{ being velocity})$$

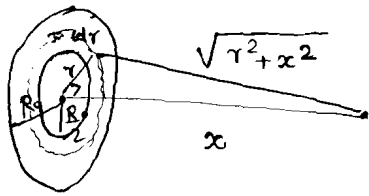

$$\therefore v = \sqrt{\frac{2K.E.}{m}} = \sqrt{\frac{2(5.53 \times 10^6 \text{ eV})(1.6 \times 10^{-19} \text{ J/eV})}{6.64 \times 10^{-27} \text{ Kg}}} = 1.63 \times 10^7 \text{ m/sec}$$

23.75. The electrons starts off with a velocity  $v$  and come to rest due to the electric interaction. The loss in kinetic energy is the one which is the work done by the electrostatic field.

$$\frac{1}{2} m v^2 - 0 = qV$$

$$\therefore v = \sqrt{\frac{2qV}{m}} = \sqrt{\frac{2 \times (1.6 \times 10^{-19} \text{ C}) \times (-3.02 \text{ V})}{9.11 \times 10^{-31} \text{ Kg}}} = 1.03 \times 10^6 \text{ m/s}$$

23.82.

$$\text{charge density} = \sigma = \frac{Q}{\pi R_0^2 - \frac{\pi R_0^2}{4}}$$

$$= \frac{4Q}{3\pi R_0^2}$$

We choose a small ring of thickness  $dr$  at a radius  $r$  and find potential due to that ring and finally add it up for all such values of  $r$ .

Amount of charge on it =  $(2\pi r) (dr) \sigma$

$\downarrow$  circumference of ring  $\rightarrow$  Thickness of ring

$$= 2\pi\sigma r dr$$

$$dV = \frac{1}{4\pi\epsilon_0} \frac{2\pi\sigma r dr}{\sqrt{r^2+x^2}} = \frac{2\pi\sigma r dr}{4\pi\epsilon_0 \sqrt{r^2+x^2}}$$

$$V = \int_{\frac{R_0}{2}}^{R_0} \frac{2\pi\sigma}{4\pi\epsilon_0} \frac{r dr}{\sqrt{r^2+x^2}}$$

$$r^2 + x^2 = t^2$$

$$r dr = t dt$$

$$= \int_{\frac{\sqrt{R_0^2+x^2}}{2}}^{\sqrt{R_0^2+x^2}} \frac{2\pi\sigma}{4\pi\epsilon_0} \frac{t dt}{t}$$

$r$	$R_0$	$R_0/2$
$t$	$\sqrt{R_0^2+x^2}$	$\sqrt{x^2 + R_0^2/4}$

$$= \frac{2\pi\sigma}{4\pi\epsilon_0} t \Big|_{\frac{\sqrt{R_0^2+x^2}}{2}}^{\sqrt{R_0^2+x^2}} = \frac{2\pi\sigma}{4\pi\epsilon_0} \left( \sqrt{R_0^2+x^2} - \sqrt{\frac{R_0^2}{4} + x^2} \right)$$

$$= \frac{2\pi}{4\pi\epsilon_0} \cdot \frac{4Q}{3\pi R_0^2} \left( \sqrt{R_0^2+x^2} - \sqrt{\frac{R_0^2}{4} + x^2} \right)$$

$$= \frac{2Q}{3\pi\epsilon_0 R_0^2} \left( \sqrt{R_0^2+x^2} - \sqrt{\frac{R_0^2}{4} + x^2} \right)$$

24.2. We know the relation between charge and capacitance -  
 $Q = CV = (12.5 \times 10^{-6} \text{ F})(12) = 1.51 \times 10^{-4} \text{ C}$

24.5. The total charge in the whole process is conserved. In the second configuration the voltage across the two capacitors should be same as they are connected by wires without any resistance between them. In the initial case -

$$Q = C_1 V_{\text{initial}}$$

In the final case -

$$V_{\text{final}} = \frac{Q_1}{C_1} = \frac{Q_2}{C_2}$$

$$\therefore Q_1 + Q_2 = (C_1 + C_2) V_{\text{final}}$$

$$Q = Q_1 + Q_2$$

$$C_1 V_{\text{initial}} = (C_1 + C_2) V_{\text{final}}$$

$$\therefore C_1 (V_{\text{initial}} - V_{\text{final}}) = C_2 V_{\text{final}}$$

$$\therefore C_2 = C_1 \left( \frac{V_{\text{ini.}}}{V_{\text{fin.}}} - 1 \right) = (7.7 \times 10^{-6} \text{ F}) \left( \frac{125 \text{ V}}{15 \text{ V}} - 1 \right) = 5.6 \times 10^{-5} \text{ F} \\ = 56 \mu\text{F}$$

24.15. We assume an uniform electric field between the plates i.e.  $V = E d$ .

$$\text{Using } C = \frac{Q}{V} = \frac{A \epsilon_0}{d}$$

$$\therefore Q_{\text{max}} = CV = \frac{A \epsilon_0}{d} \times V = \frac{A \epsilon_0}{d} \times E d = A \epsilon_0 E$$

$$= (8.85 \times 10^{-12} \text{ F/m}) (6.8 \times 10^{-4} \text{ m}^2) (3 \times 10^6 \text{ V/m}) = 1.8 \times 10^{-8} \text{ C}$$

24.22. a) Net capacitance when capacitors are connected in parallel-  
 $C_{\text{eq}} = C_1 + C_2 + C_3 + C_4 + C_5 + C_6 = 6(3.8 \times 10^{-4} \text{ F}) = 2.28 \times 10^{-3} \text{ F}$

b) Net capacitance when capacitors are connected in series-  
 $\frac{1}{C_{\text{net}}} = \left( \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \frac{1}{C_4} + \frac{1}{C_5} + \frac{1}{C_6} \right) = \frac{6}{3.8 \times 10^{-4} \text{ F}}$

$$\therefore C_{\text{net}} = \frac{3.8 \times 10^{-4} \text{ F}}{6} = 6.3 \times 10^{-5} \text{ F}$$

24.29. a)  $C_1, C_2$  are in series which is in parallel <sup>with</sup>  $C_3$ . This is then in series with  $C_4$ . We now find equivalent capacitance.

$$\frac{1}{C_{12}} = \frac{1}{C} + \frac{1}{C} = \frac{2}{C} \quad \therefore C_{12} = \frac{C}{2}$$

$$C_{123} = C_{12} + C_3 = \frac{C}{2} + C = \frac{3C}{2}$$

$$\frac{1}{C_{1234}} = \frac{1}{C_{123}} + \frac{1}{C_4} = \frac{2}{3C} + \frac{1}{C} = \frac{5}{3C}$$

$$\therefore C_{1234} = \frac{3C}{5}$$

b) The charge on capacitor  $C_{1234}$  is  $Q = C_{1234} V = \frac{3CV}{5}$ . The same charge is placed on the other series components of  $C_{1234}$ .

$$Q_{123} = \frac{3}{5} CV = C_{123} V_{23} \quad \therefore V_{23} = \frac{2}{5} V$$

$$Q_4 = \frac{3}{5} CV = C_4 V_4 \quad \therefore V_4 = \frac{3}{5} V$$

The voltage across the equivalent capacitance  $C_{123}$  is the voltage across both of its parallel components as they are in parallel.

However the sum of the charges across two parallel components of  $C_{123}$  is the same as the total charge on the two components  $\frac{3}{5} CV$ .

$$V_{123} = \frac{2}{5} V = V_{12} \quad Q_{12} = C_{12} V_{12} = \frac{C}{2} \cdot \frac{2}{5} V = \frac{CV}{5}$$

$$V_{123} = \frac{2}{5} V = V_3 \quad Q_3 = C_3 V_3 = C \left( \frac{2}{5} V \right) = \frac{2CV}{5}$$

Charge on  $C_{12}$  is the charge on both its series components -

$$Q_{12} = \frac{1}{5} CV = Q_1 = C_1 V_1 \quad \therefore V_1 = \frac{V}{5}$$

$$Q_{12} = \frac{1}{5} CV = Q_2 = C_2 V_2 \quad \therefore V_2 = \frac{V}{5}$$

24.31. When the switch is down the charge on  $C_2$  is given as -

$$Q_2 = C_2 V_0$$

When the switch is moved up, the charge on  $C_2$  will flow to  $C_1$  until the voltage on two capacitors is equal.

$$V = \frac{Q_2'}{C_2} = \frac{Q_1'}{C_1} \quad \therefore Q_2' = Q_1' \frac{C_2}{C_1}$$

Since charge is conserved, the total charge should equal the initial charge.

$$Q_1' + Q_2' = Q_2$$

$$Q_1' + Q_1' \frac{C_2}{C_1} = C_2 V_0$$

$$\therefore Q_1' \left( 1 + \frac{C_2}{C_1} \right) = C_2 V_0$$

$$Q_1' = \frac{C_2 V_0}{(C_1 + C_2)} \times C_1$$

$$Q_2' = \frac{C_2}{C_1} \times \frac{C_1 C_2 V_0}{(C_1 + C_2)}$$

$$= \frac{C_2^2 V_0}{(C_1 + C_2)}$$

24.41. The energy stored in a capacitor is given as -

$$E = \frac{1}{2} CV^2 = \frac{1}{2} (2.8 \times 10^{-9} \text{ F}) (2200 \text{ V})^2 = 6.8 \times 10^{-3} \text{ J}$$

24.44. a) The charges on the capacitors remains constant when the distance is changed between the capacitors. However the capacitance changes.

$$\frac{U_2}{U_1} = \frac{\frac{1}{2} C_1 V_1^2}{\frac{1}{2} C_2 V_2^2} = \frac{\frac{1}{2} \frac{Q^2}{C_2}}{\frac{1}{2} \frac{Q^2}{C_1}} = \frac{C_1}{C_2} = \frac{\frac{A \epsilon_0}{d}}{\frac{A \epsilon_0}{3d}} = \frac{3}{1}$$

$$( \because V = \frac{Q}{C} )$$

b) Amount of work done is the change in the energy in capacitors -

$$U_2 - U_1 = 3U_1 - U_1 = 2U_1 = 2 \frac{Q^2}{2C_1} = \frac{Q^2}{C_1} = \frac{Q^2}{\frac{A\epsilon_0}{d}}$$

$$= \frac{dQ^2}{A\epsilon_0}$$
