The life of top quarks

The SM under attack

▶ The Standard Model is a fantastic success

Three Generations of Matter (Fermions)

	I	II	III	
mass →	3 MeV	1.24 GeV	172.5 GeV	0
charge →	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{2}{3}$	0
spin →	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
name →	u up	c charm	t top	γ photon
	6 MeV	95 MeV	4.2 GeV	0
	$-\frac{1}{3}$	$-\frac{1}{3}$	$-\frac{1}{3}$	0
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
	d down	s strange	b bottom	g gluon
	<2 eV	<0.19 MeV	<18.2 MeV	90.2 GeV
	0	0	0	0
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	Z^0 weak force
	0.511 MeV	106 MeV	1.78 GeV	80.4 GeV
	-1	-1	-1	± 1
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1
	e electron	μ muon	τ tau	W^\pm weak force

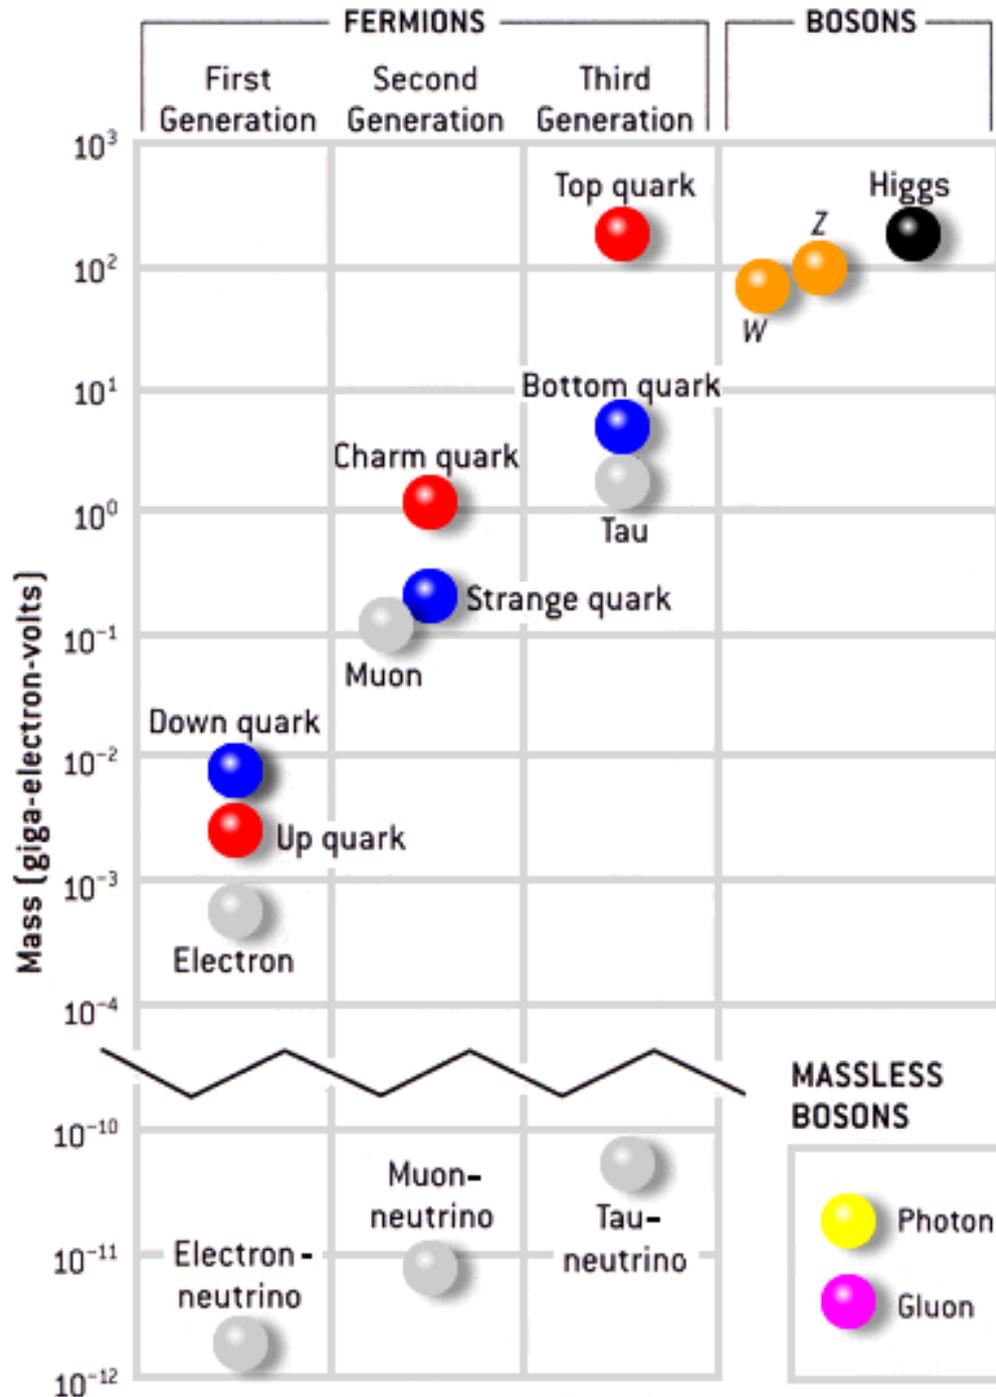

▶ But recently: Neutrino masses, dark matter

▶ So we know it is not a complete description of Nature

▶ Many unanswered questions:

- Why three generations?
- What is the mechanism responsible for particles' masses?
- Why that hierarchy of masses?
- What's with so many free parameters?
- Gravity is not in the picture
- Unification of three couplings is not possible

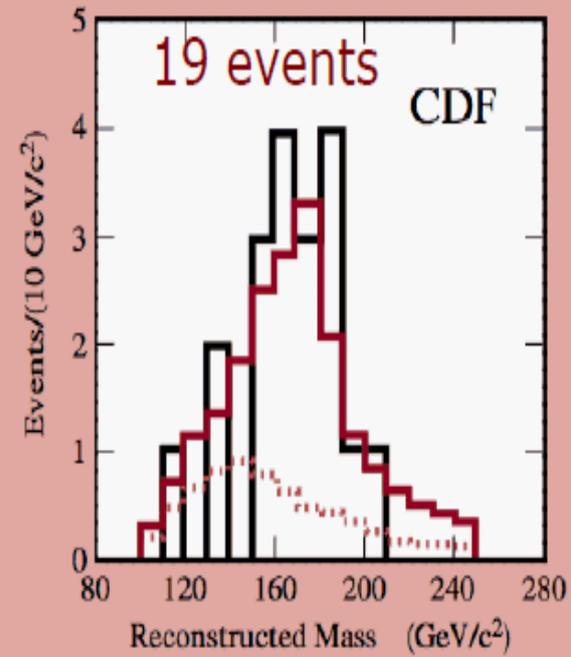

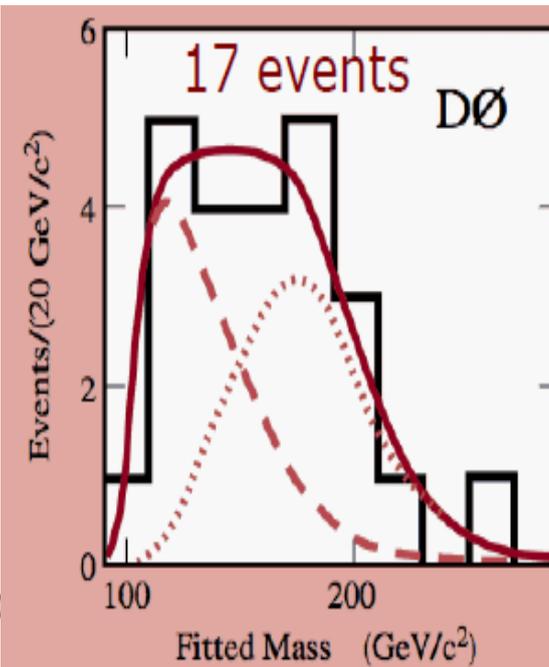

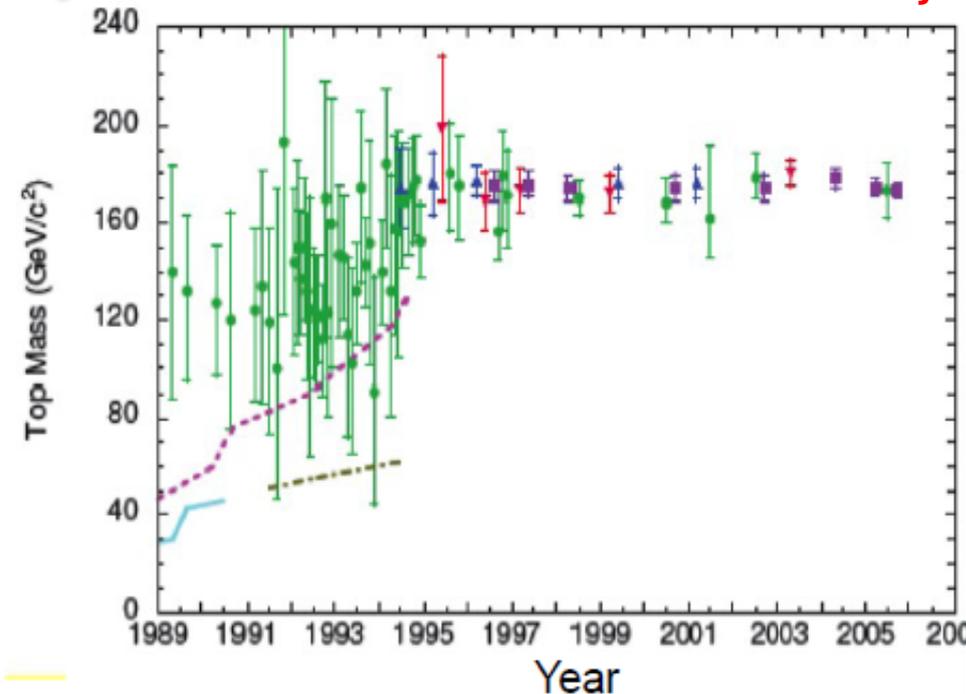

Top quark: not just the sixth quark

- ▶ Heaviest known particle
40 times heavier than b
As heavy as one Tungsten atom
- ▶ Only quark that decays before hadronization
lifetime $\sim 10^{-25}s$
- ▶ Couples strongly to EWSB boson
Related to the origin of mass?
- ▶ Unique laboratory to study the SM and beyond

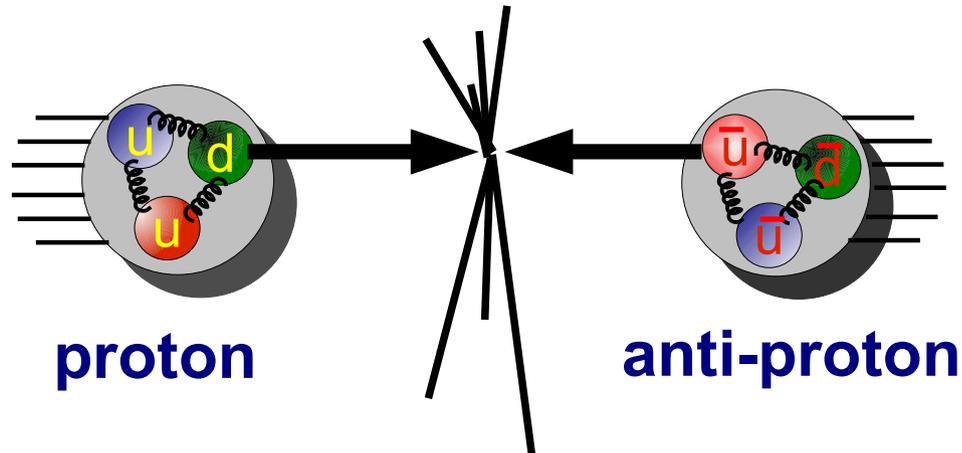

A brief history of top

- ▶ 1976: Discovery of Upsilon ($b\bar{b}$ meson): a 5th quark means there is a 6th
A race to find the 6th quark begins:
- ▶ 1984: Petra e^+e^- (Germany) $m_t > 23$ GeV
- ▶ 1988: UA1 (CERN) $m_t > 44$ GeV
- ▶ 1992: CDF (Fermilab) $m_t > 91$ GeV, DØ (1994) $m_t > 131$ GeV
- ▶ 1994: Electroweak fits (LEP/SLC/TeV): $155 \text{ GeV} < m_t < 185 \text{ GeV}$
- ▶ 1995: DØ and CDF announce joint discovery
 - DØ: 50 pb^{-1} , 17 events, $\sigma = 6.4 \pm 2.2 \text{ pb}$, $m_t = 199 \pm 30 \text{ GeV}$
 - CDF: 67 pb^{-1} , 19 events, $\sigma = 6.8^{+3.6}_{-2.4} \text{ pb}$, $m_t = 176 \pm 13 \text{ GeV}$
- ▶ 2009: DØ and CDF announce joint discovery of single top production

Tools of the trade

- ▶ Particle physicists use high energy colliders to probe physics at small distances

Note on units: $N[\text{collisions}] = \sigma[\text{pb}] L[\text{pb}^{-1}]$

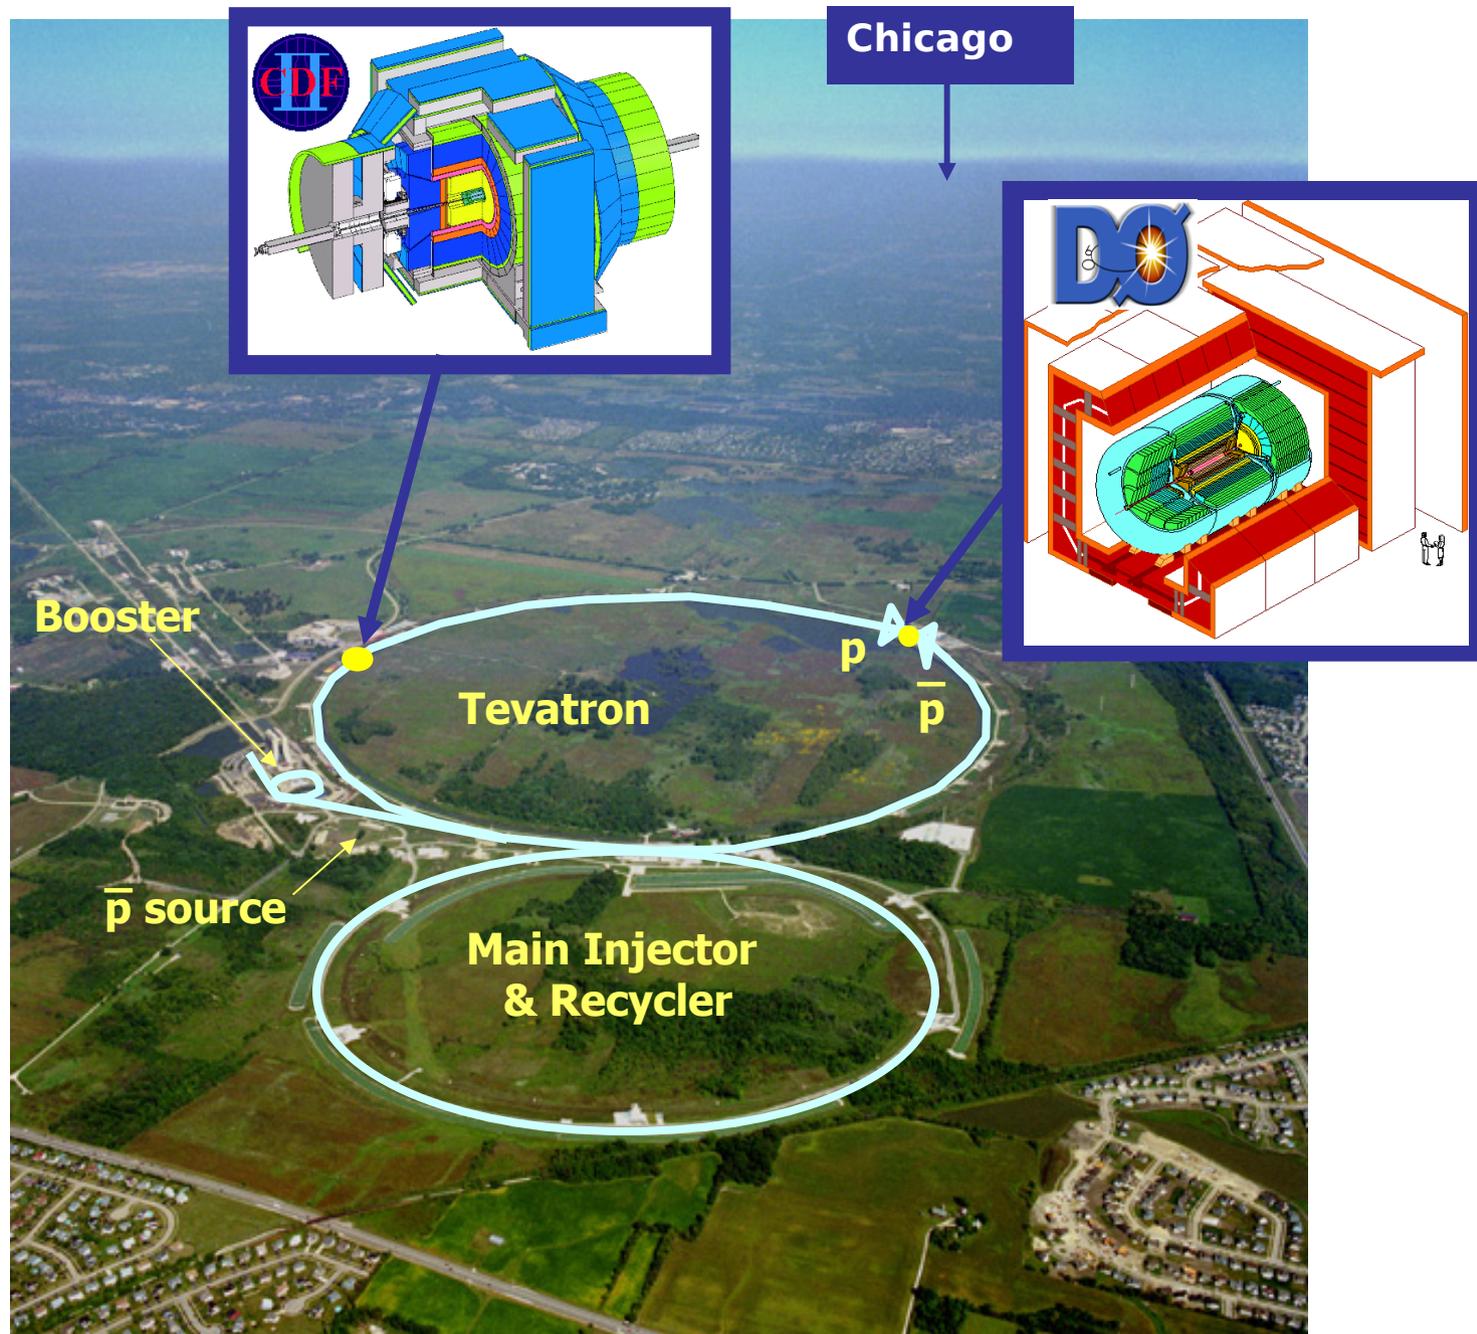

- ▶ **Picobarns** (pb) is a measure of “cross section” (σ =interaction probability). 1 barn = 10^{-24} cm².
- ▶ **Inverse picobarns** (pb⁻¹) is a measure of the “integrated luminosity” (L=collected data)

Example: 1000 pb⁻¹ = 1 fb⁻¹ = enough data to observe 1000 events of a process having 1 pb cross section

- ▶ **GeV** are used interchangeably for mass, energy, and momentum

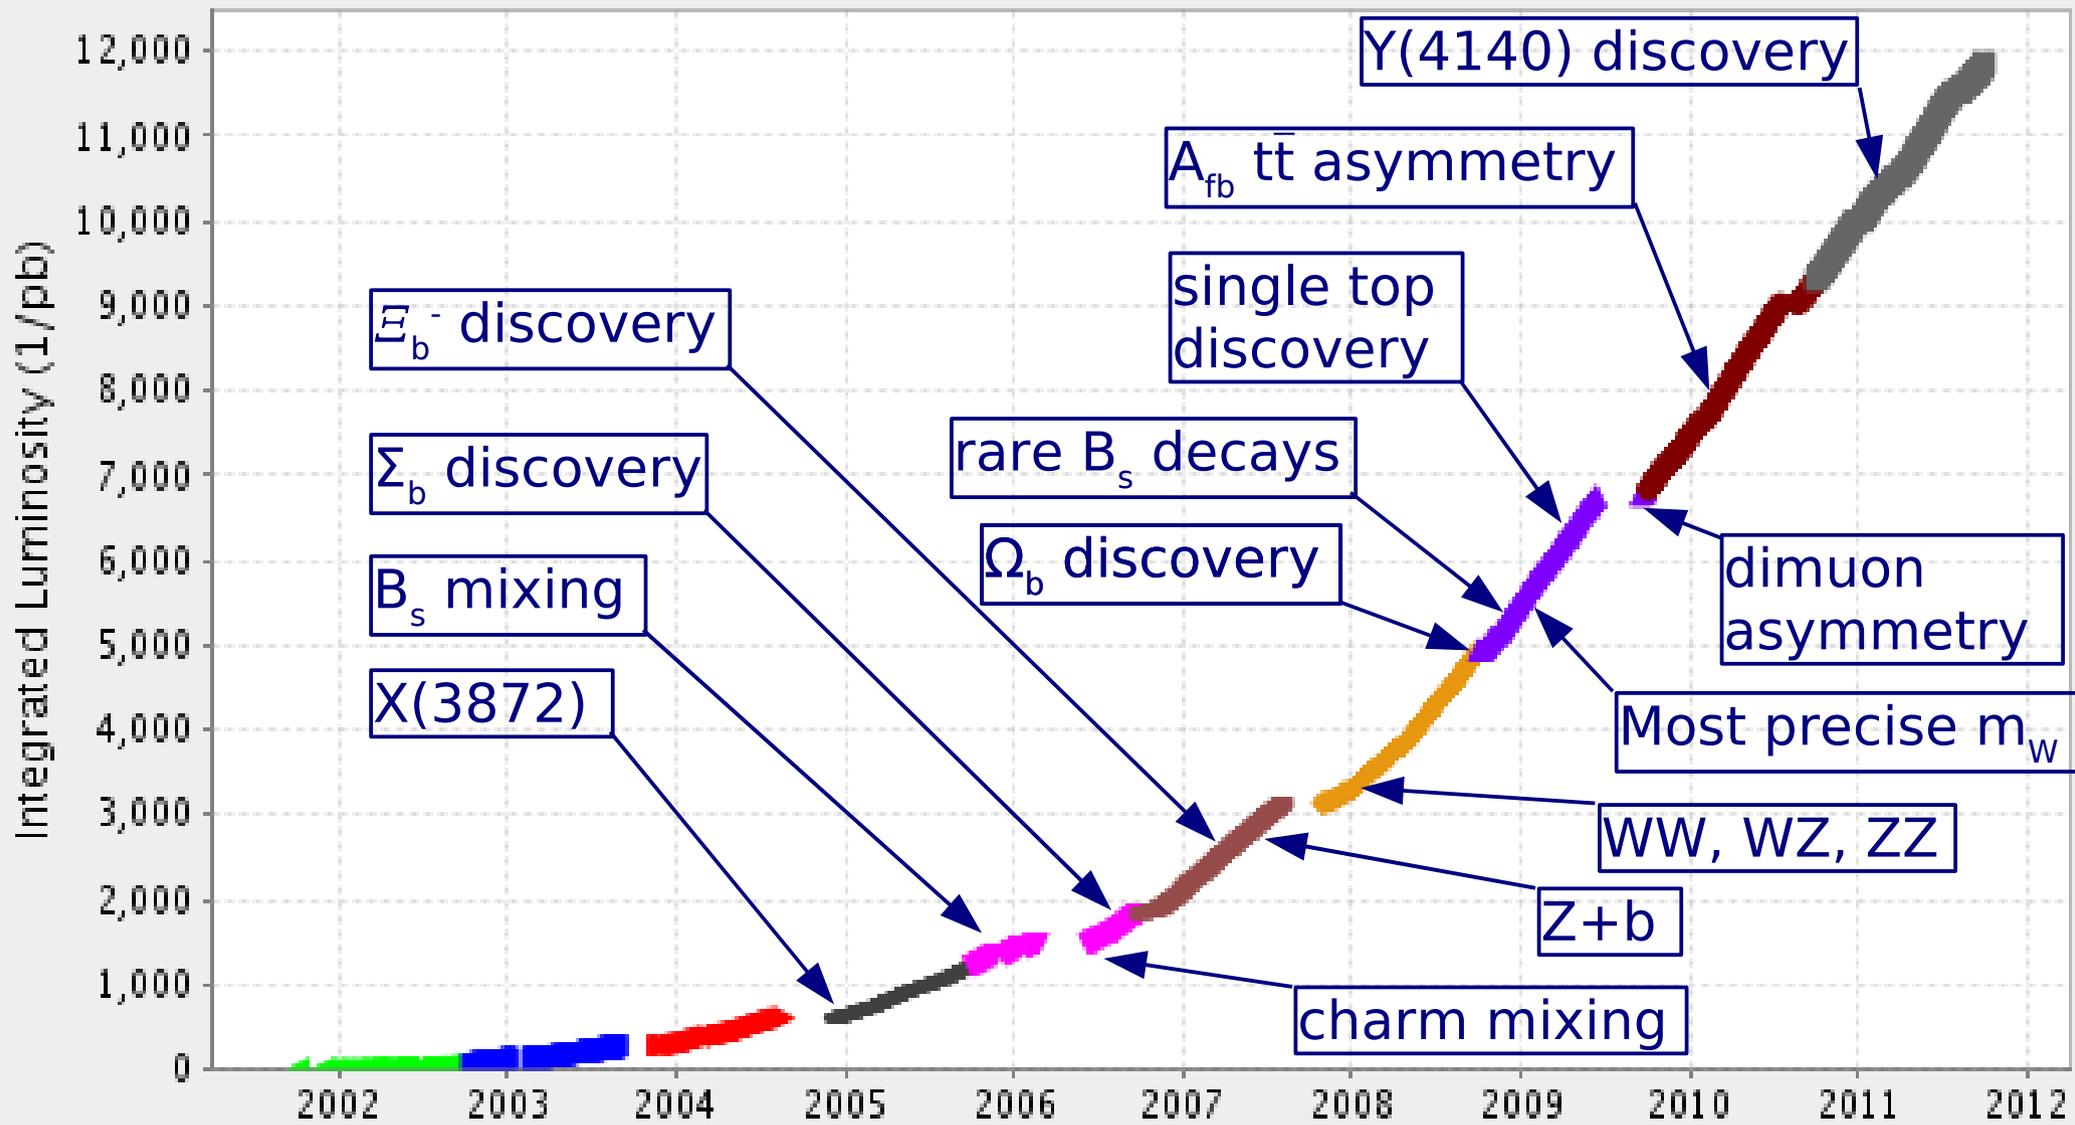

The Tevatron

- ▶ 6.3 km $p\bar{p}$ collider
- ▶ $\sqrt{s} = 1.96$ TeV
- ▶ Run I: 1987-1996
- ▶ Run II: 2002-2011
- ▶ 36x36 bunches
- ▶ 10^{11} \bar{p} per bunch
- ▶ 396 ns bunch spacing
- ▶ 1.8 M crossings/s
- ▶ $4.3 \cdot 10^{32}$ cm^2s^{-1} peak lumi
- ▶ 12 fb^{-1} delivered luminosity
- ▶ Detectors recorded data with 90% efficiency

Tevatron milestones

Integrated Luminosity **11871.03 (1/pb)**

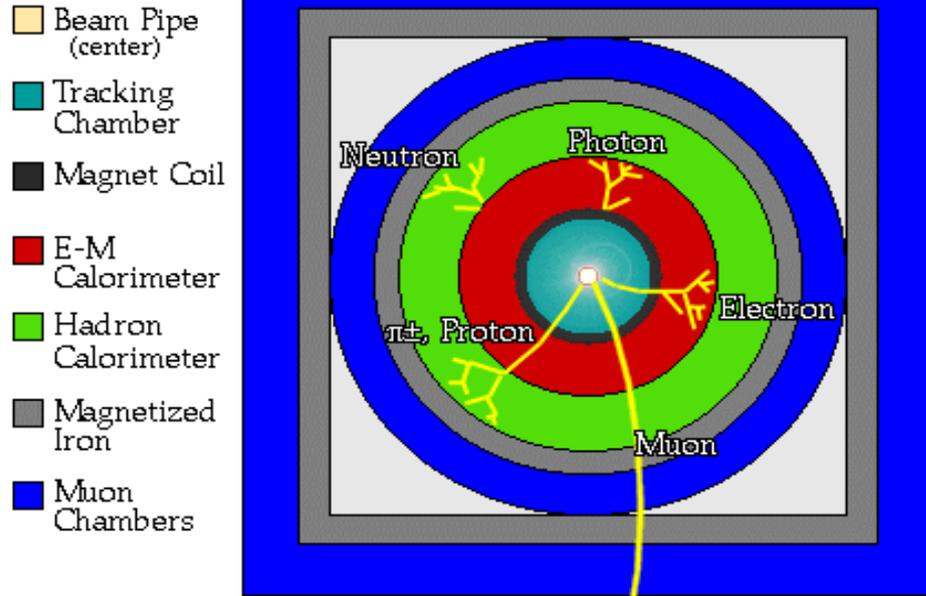

Top quark discovery

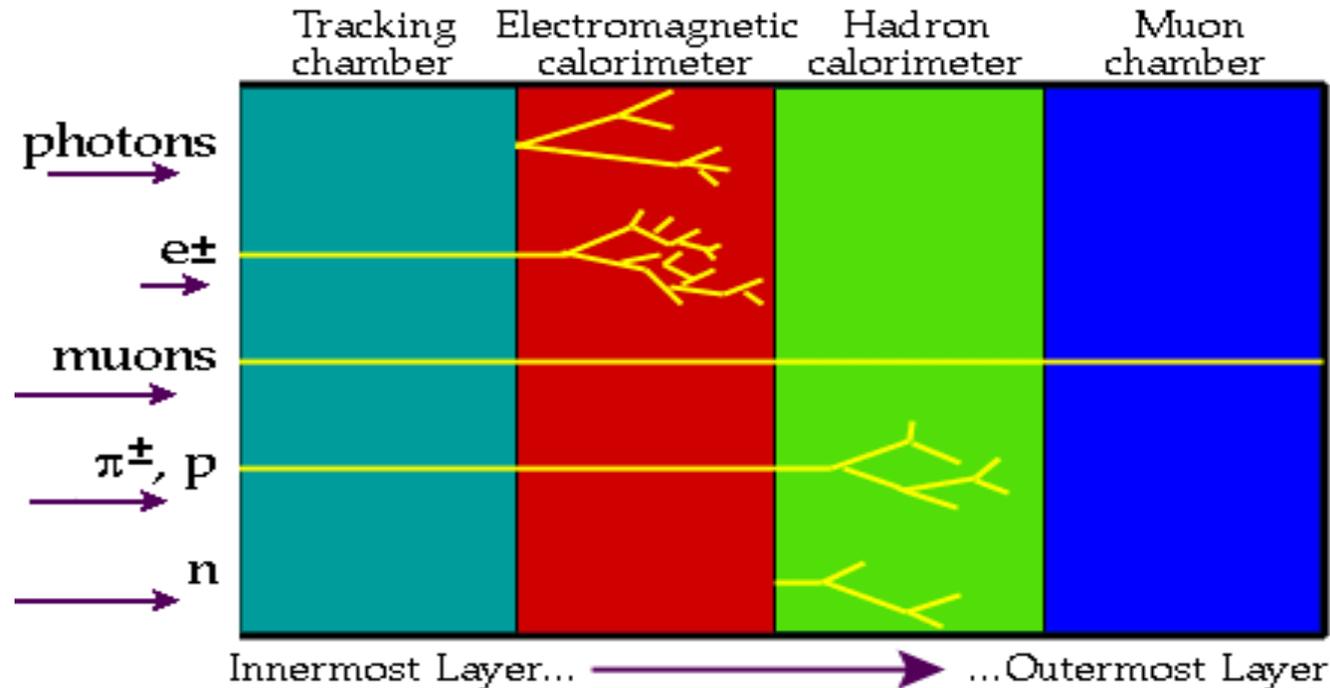

General detector and particle ID

A detector cross-section, showing particle paths

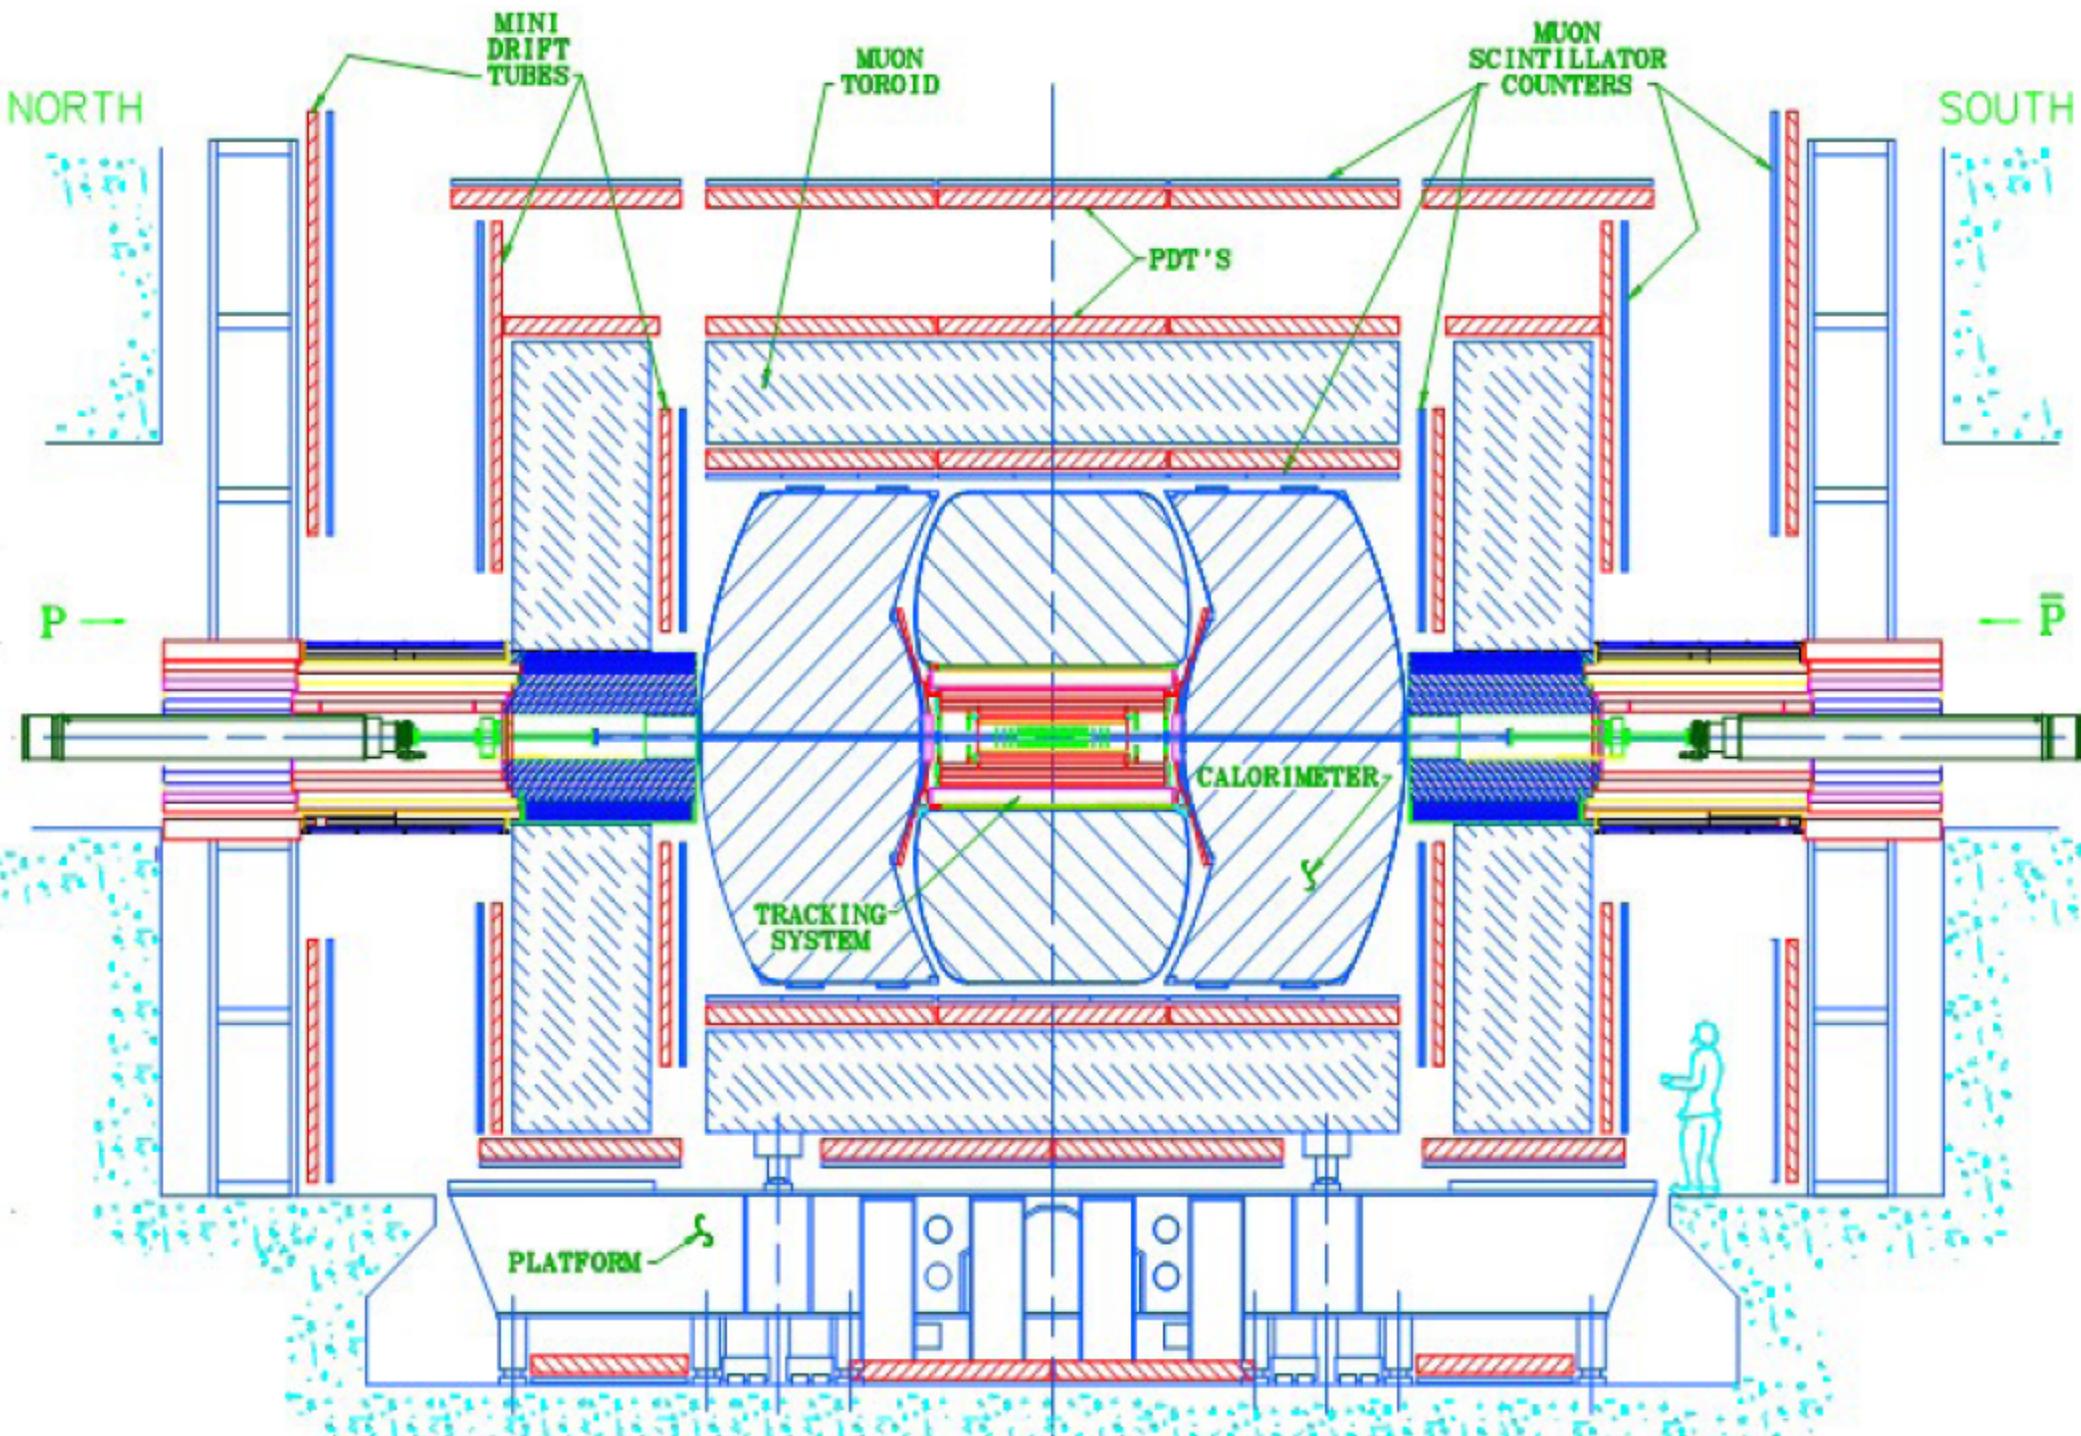

We detect particles by the EM and strong interaction fingerprints they leave behind

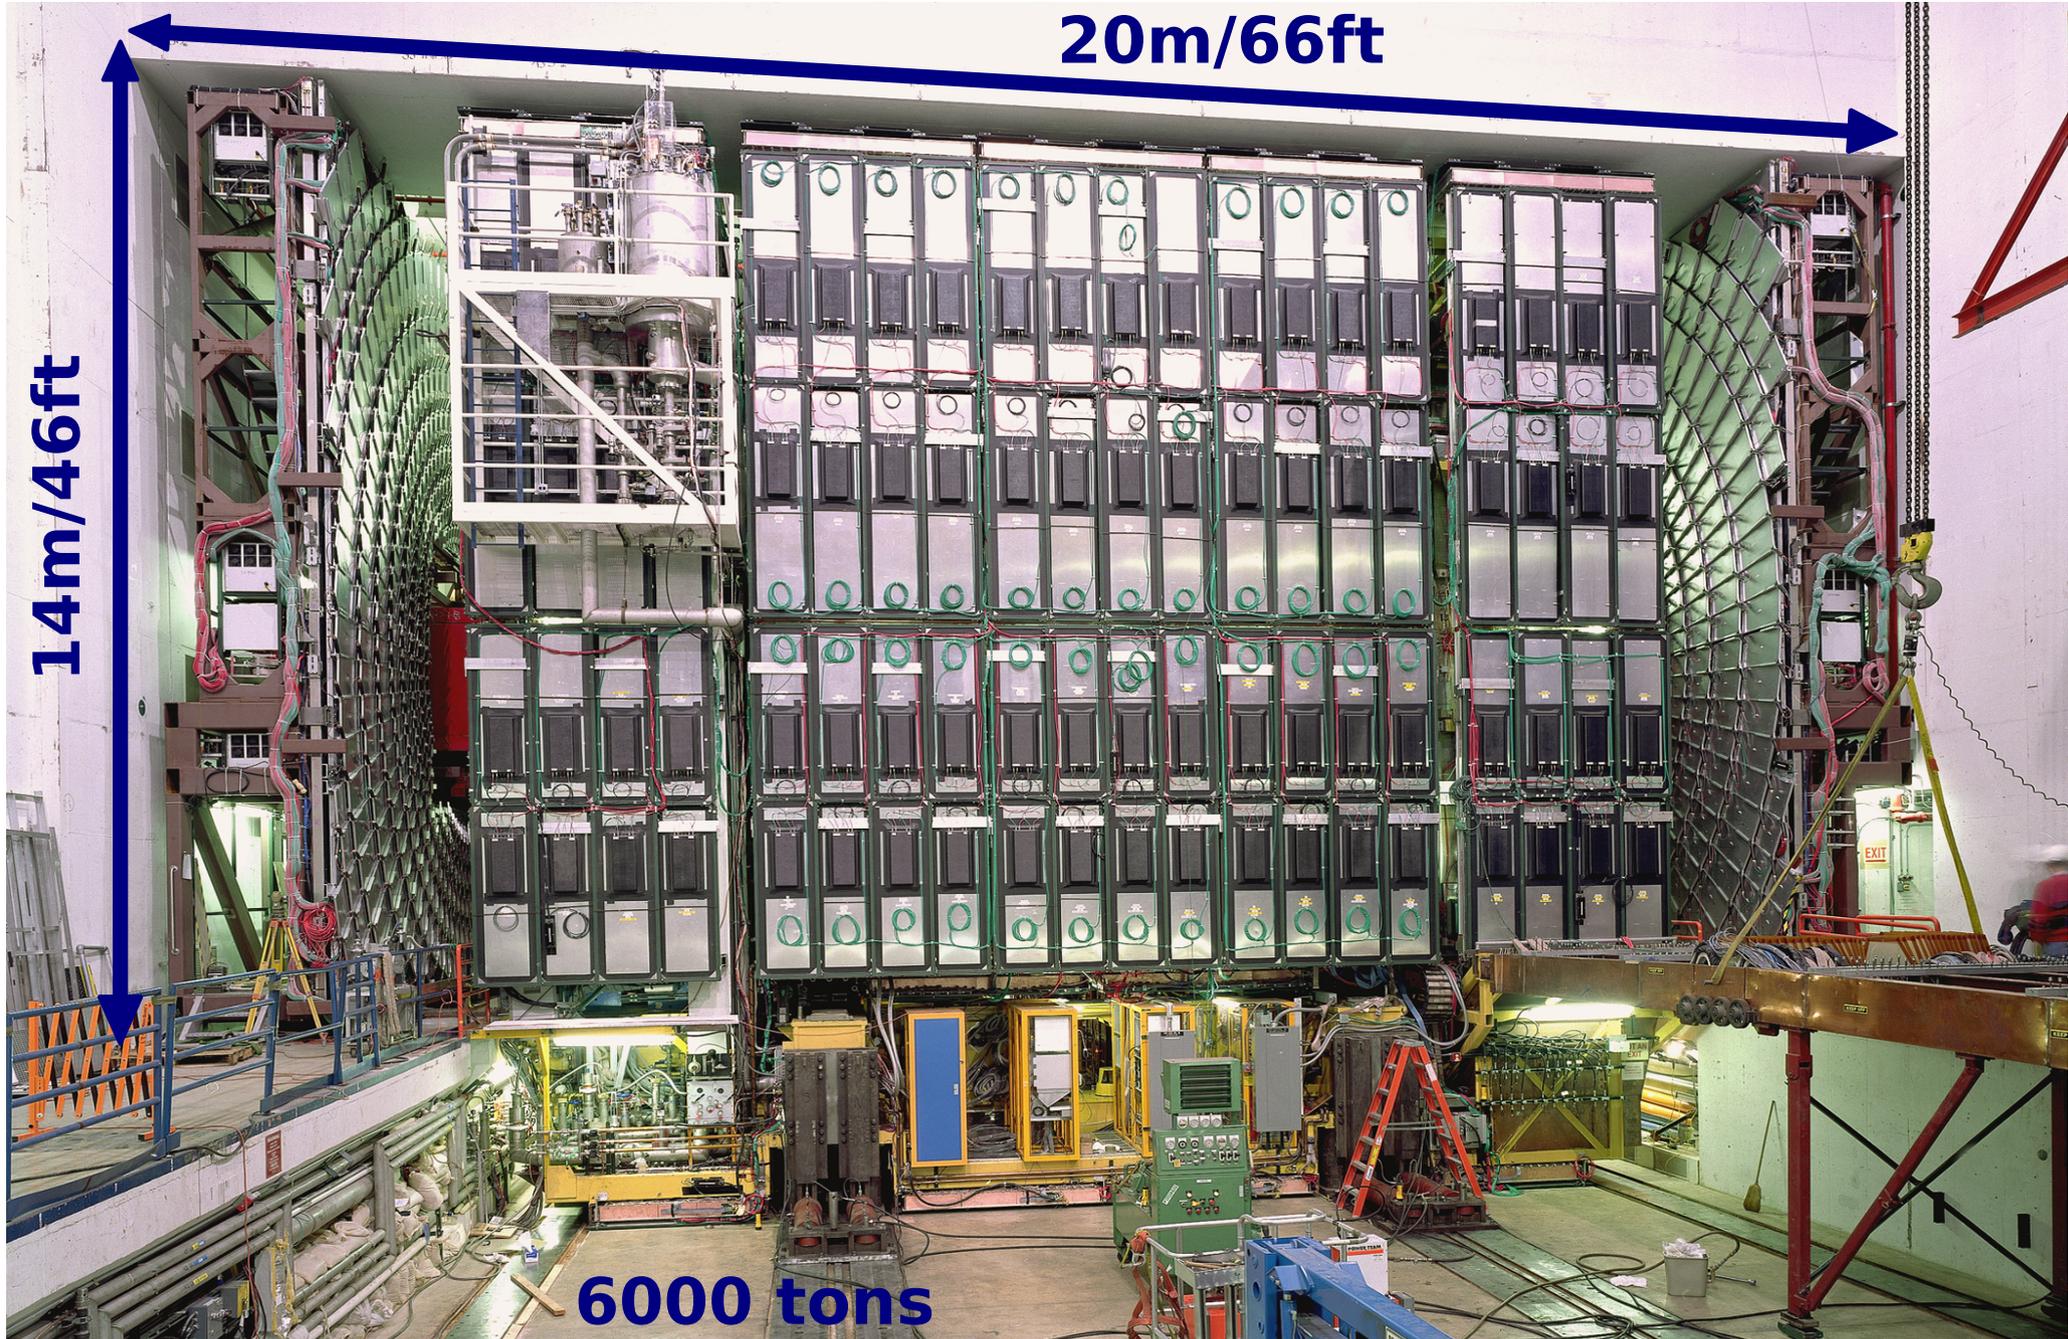

- ▶ Tracking is first (measure p_T)
- ▶ Calorimetry (EM and hadronic)
- ▶ Muons
- ▶ All the rest is neutrinos

The DØ detector

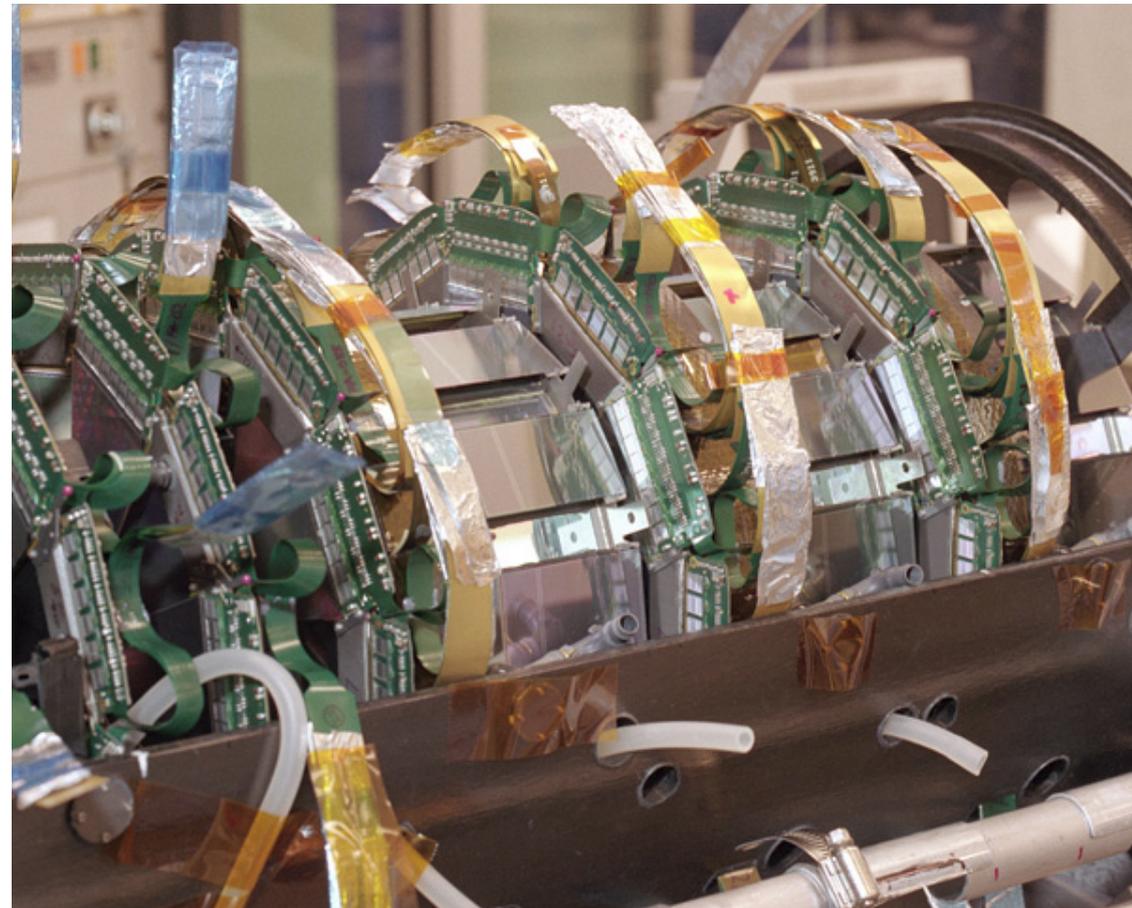

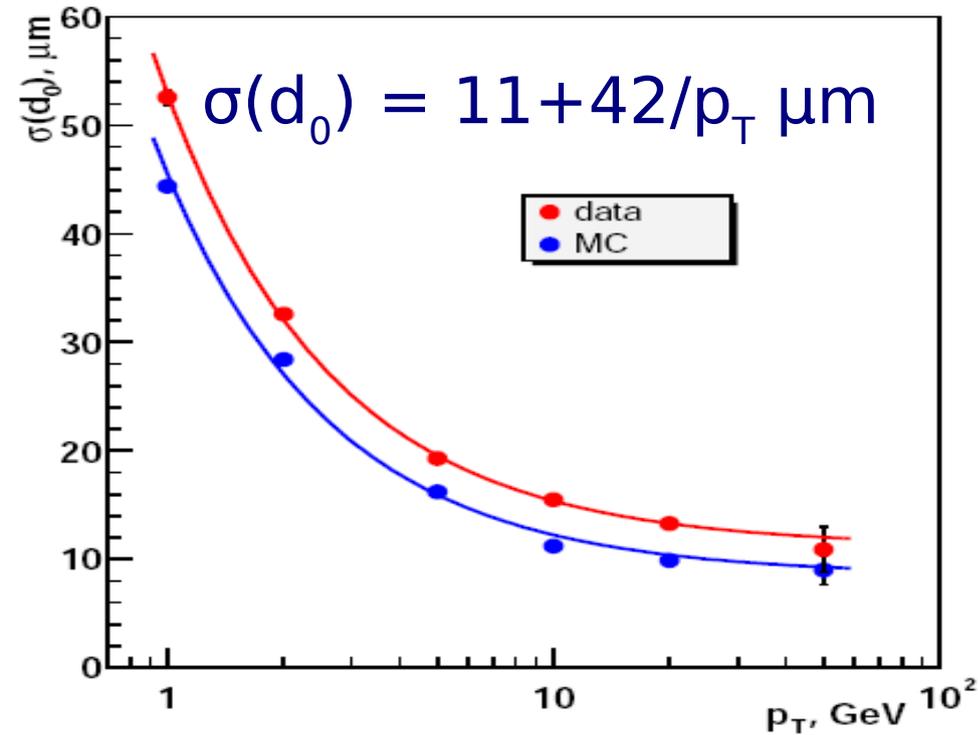

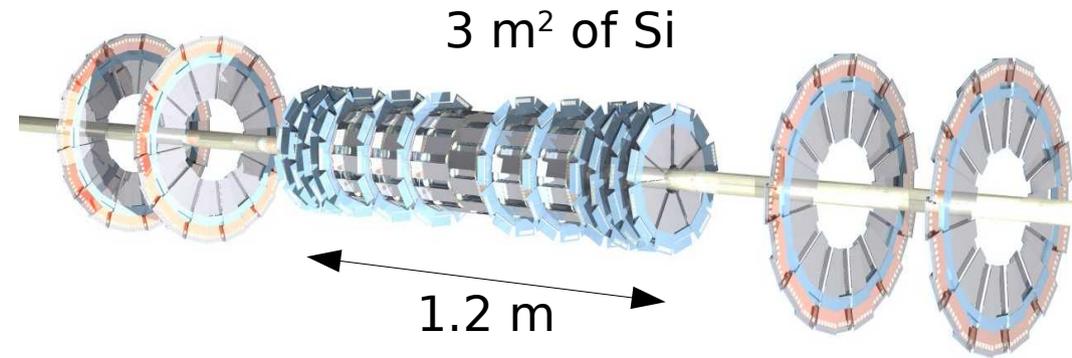

The real thing: the DØ detector

You better have good tracking

- ▶ The Silicon Microstrip Tracker allows resolutions of $\sim 10 \mu\text{m}$
- ▶ Inner radius: 1.7cm away from the interaction point

Bottom quark decays can be tagged

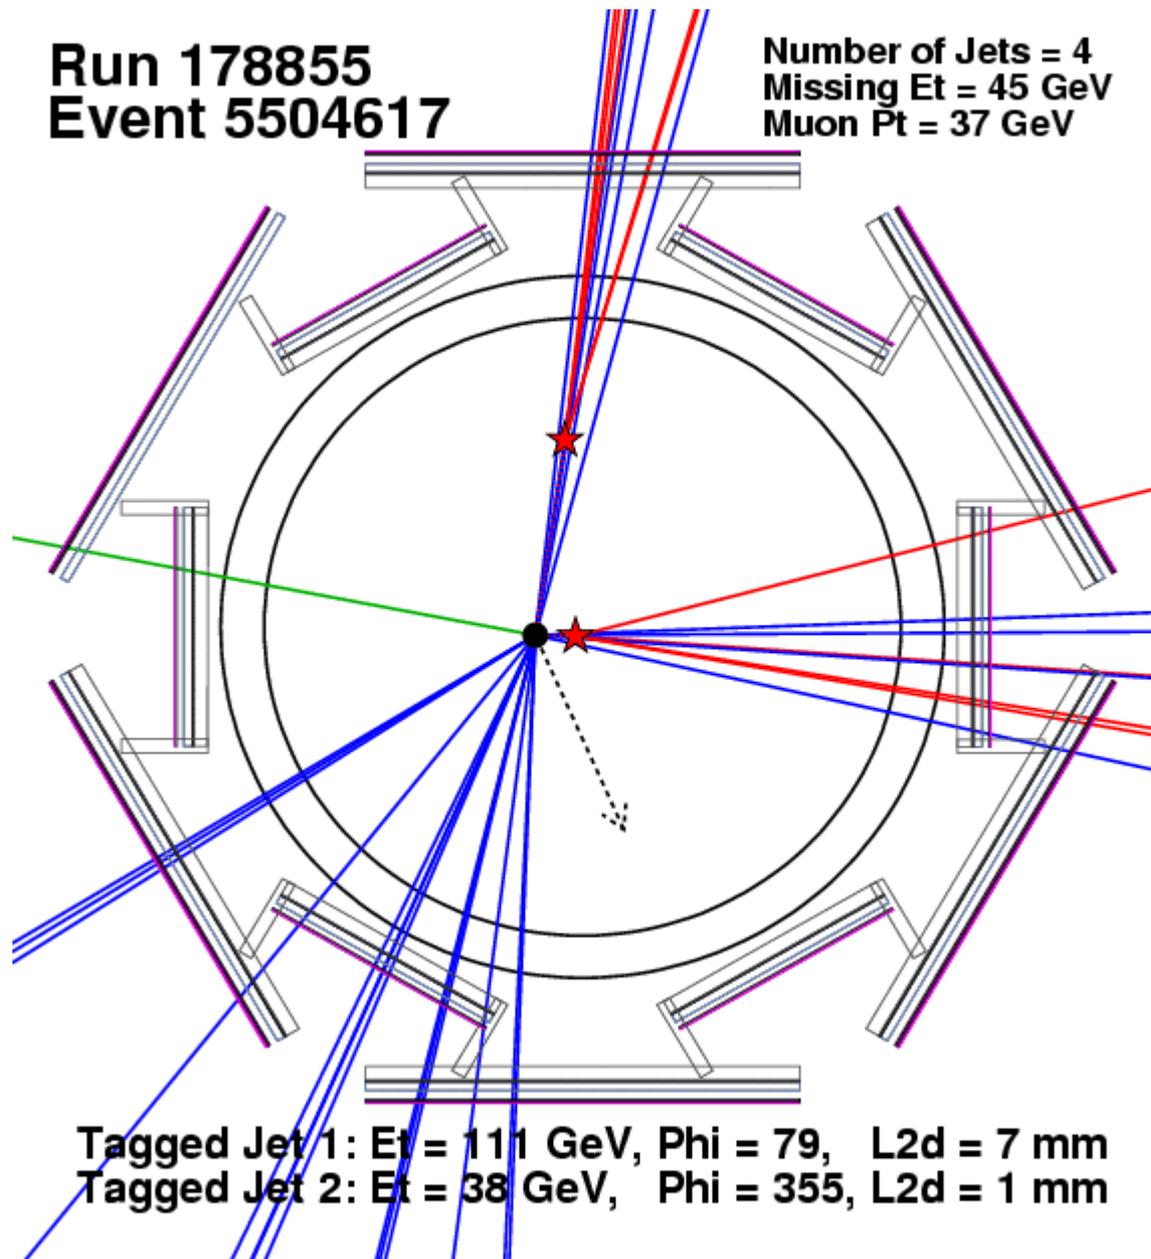

B hadrons have a lifetime:
 $\sim 10^{-12}$ s

They can travel a few mm in the detector before decaying

Signature: displaced tracks and secondary vertices

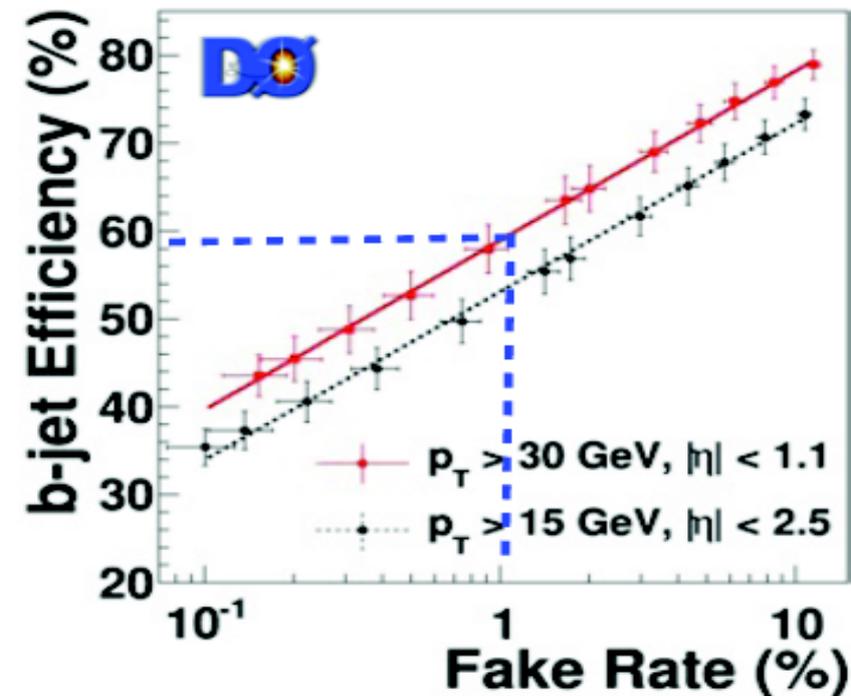

Run 178855
Event 5504617

Number of Jets = 4
Missing Et = 45 GeV
Muon Pt = 37 GeV

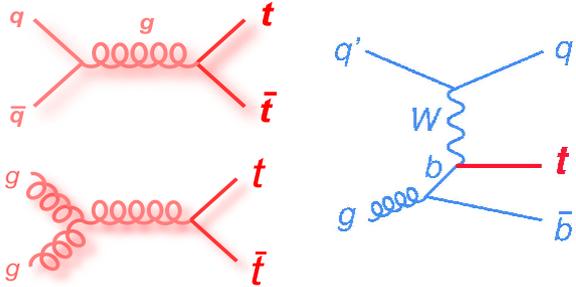

Tagged Jet 1: Et = 111 GeV, Phi = 79, L2d = 7 mm
Tagged Jet 2: Et = 38 GeV, Phi = 355, L2d = 1 mm

NIM, A620, 400 (2010)

Top quark Tevatron program

How is it produced

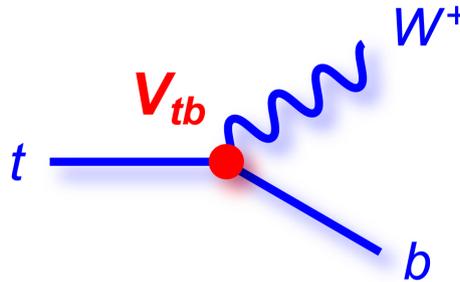

Strong force:

$$\sigma_{tt} \sim 7 \text{ pb}$$

Electroweak force:

$$\sigma_{tb+tbq} \sim 3 \text{ pb}$$

How does it decay

$$V_{tb} \sim 1$$

V-A coupling:

$$F_0 \sim 0.7$$

$$F_+ \sim 0$$

What are its intrinsic properties

Mass: 173 GeV

Width: 1.3 GeV

Charge: +2/3

Spin: 1/2

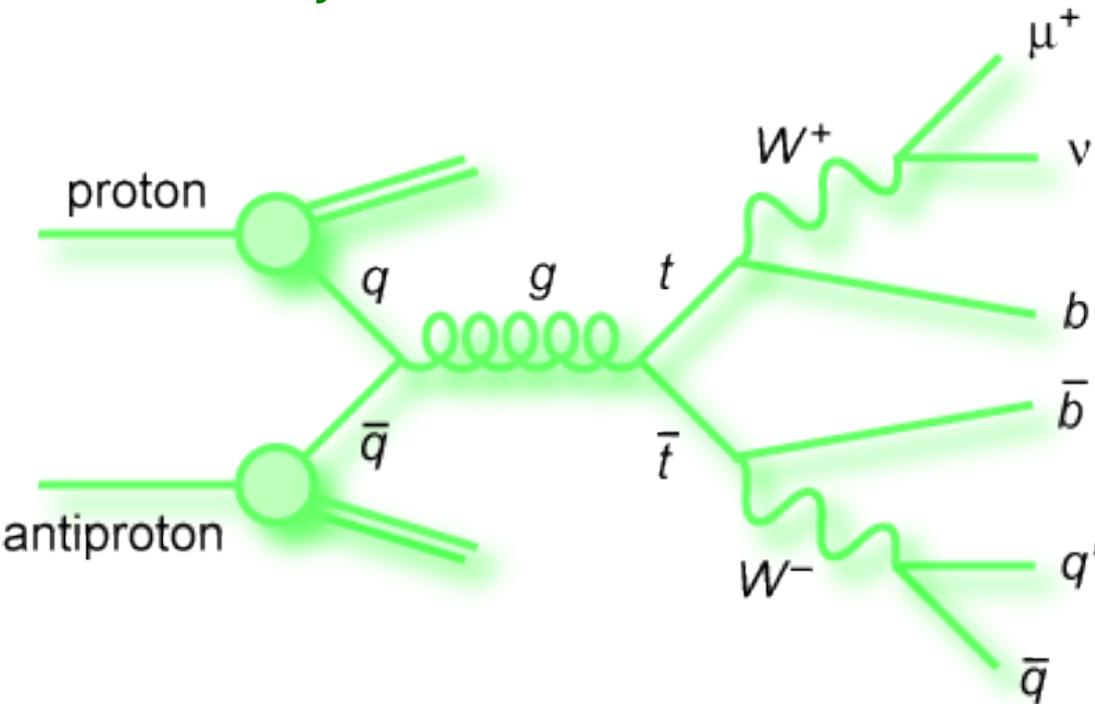

Are there signs of new physics anywhere

t', W', Z', H+, resonances, FCNC, anomalous charge...

Pair-production in ℓ +jets

► **Signal:** $t\bar{t} \rightarrow Wb Wb \rightarrow \ell\nu b qqb$

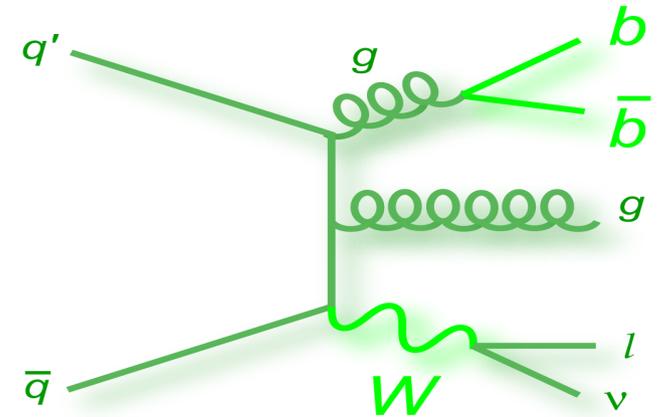

- $\sigma(t\bar{t}) = 7 \text{ pb}$
- One high energy e or μ
- Missing energy
- ≥ 4 jets
- 2 b-jets

► **Backgrounds:**

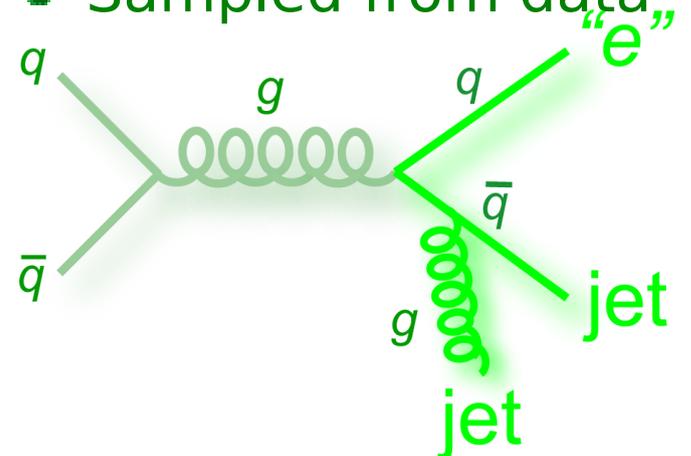

► **W+jets:** $\sigma \sim \text{o}(1000) \text{ pb}$

- From simulation
- Rate normalized to data

► **Multijets** ($\sigma \sim 10^9 \text{ pb}$)

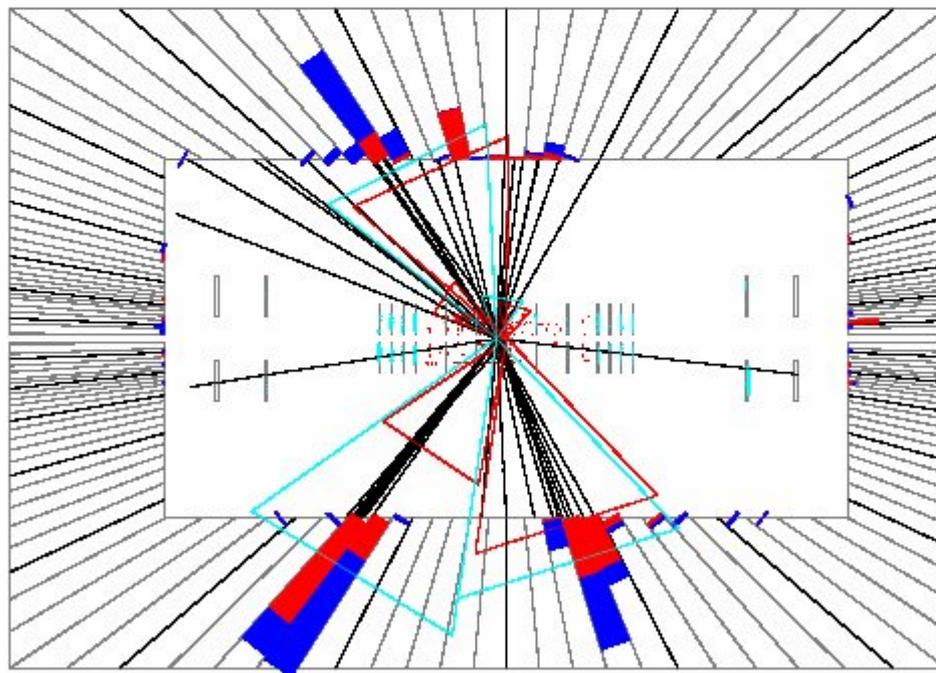

- Sampled from data

A $t\bar{t}$ candidate event in the data

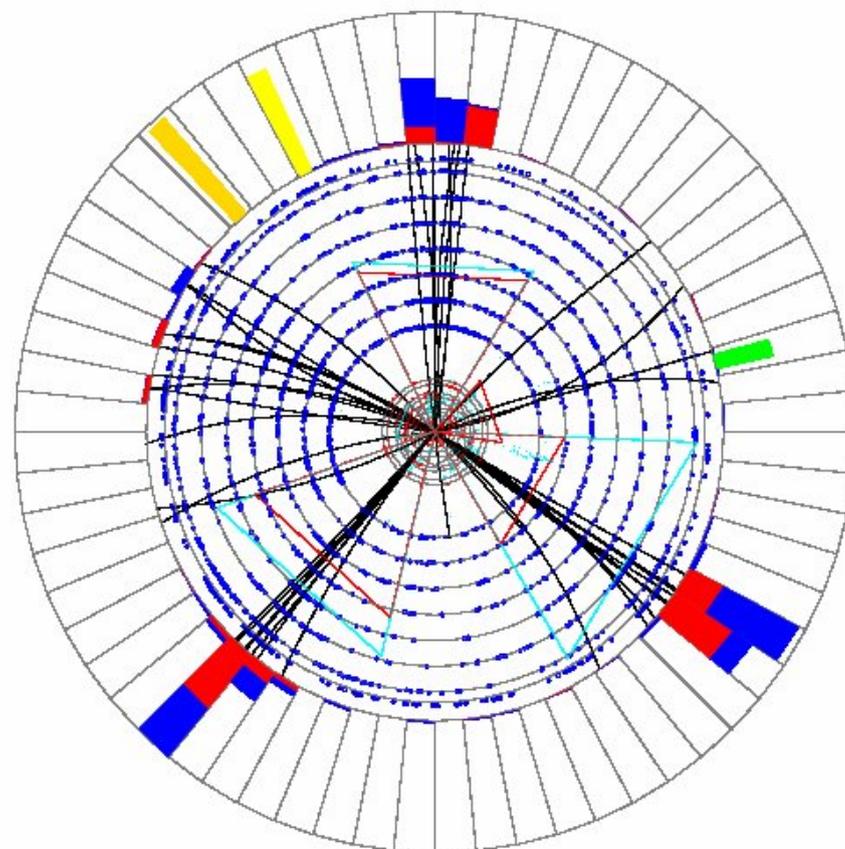

Run 238436 Evt 2624772 Fri Dec 7 16:14:24 2007

E scale: 57 GeV

Run 238436 Evt 2624772 Fri Dec 7 16:14:24 2007

ET scale: 64 GeV

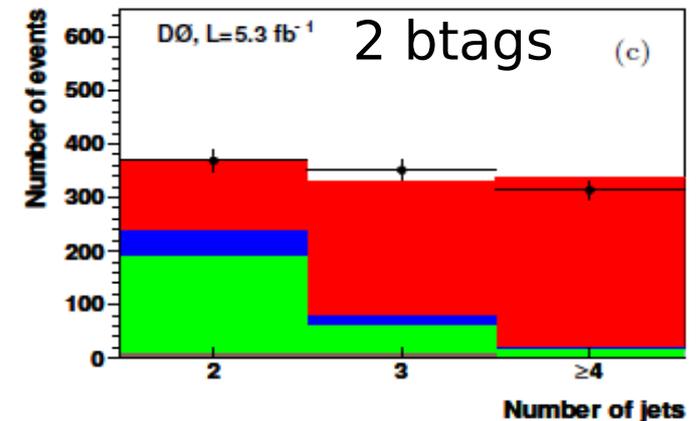

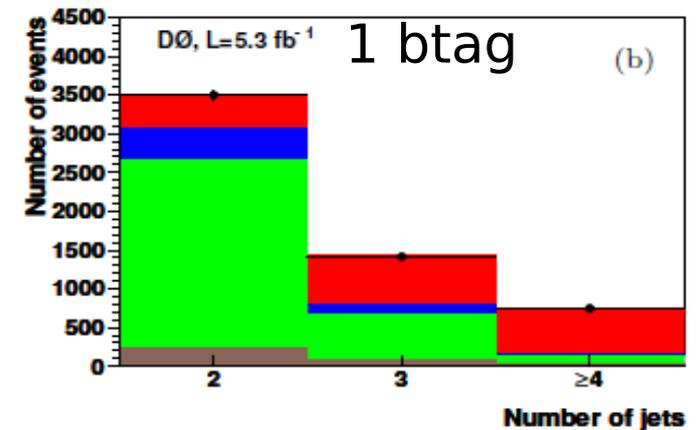

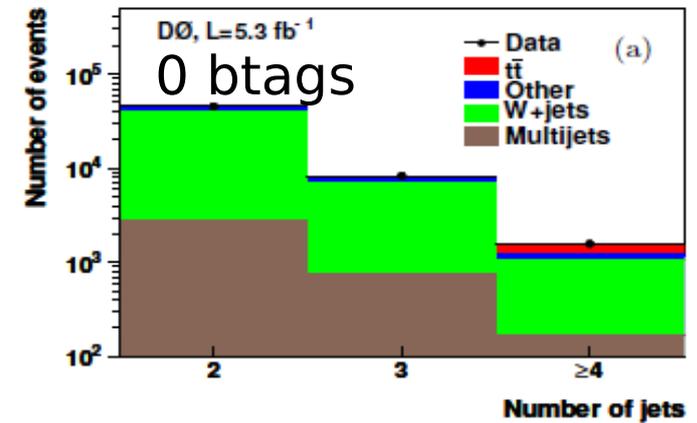

Measuring the $t\bar{t}$ cross section

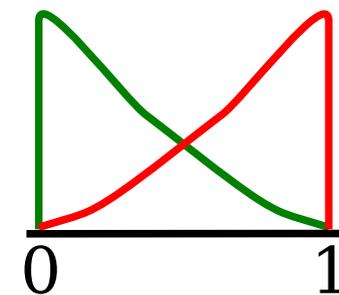

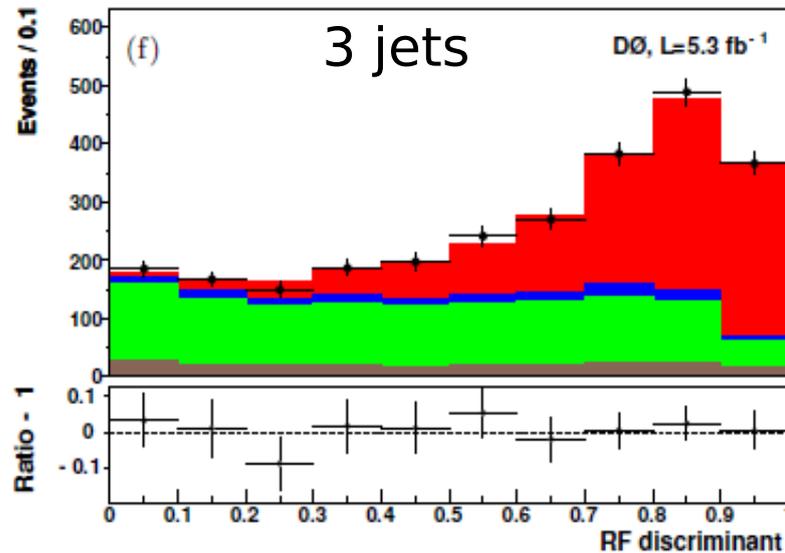

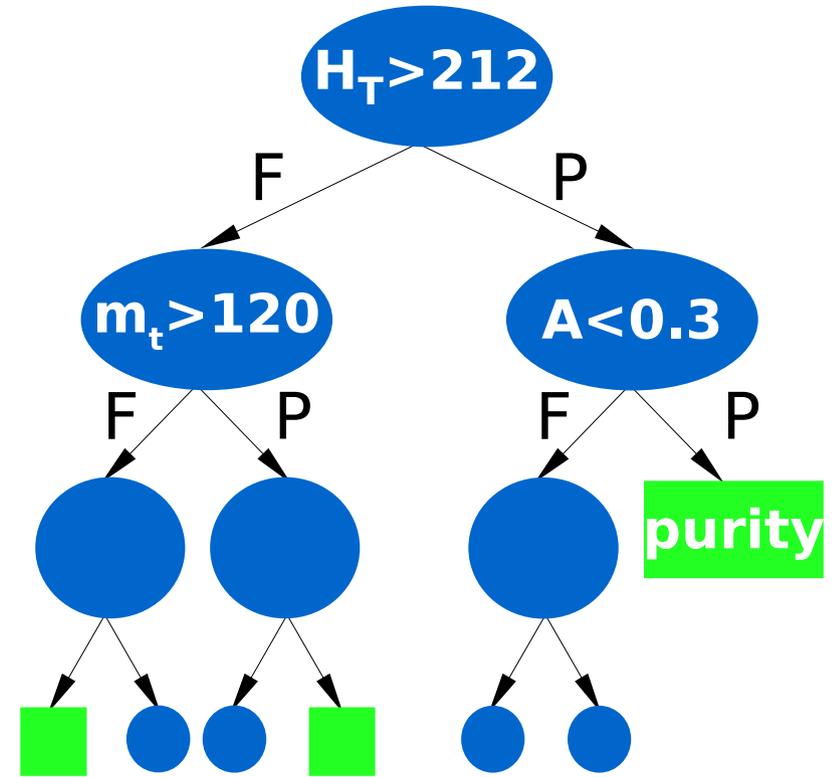

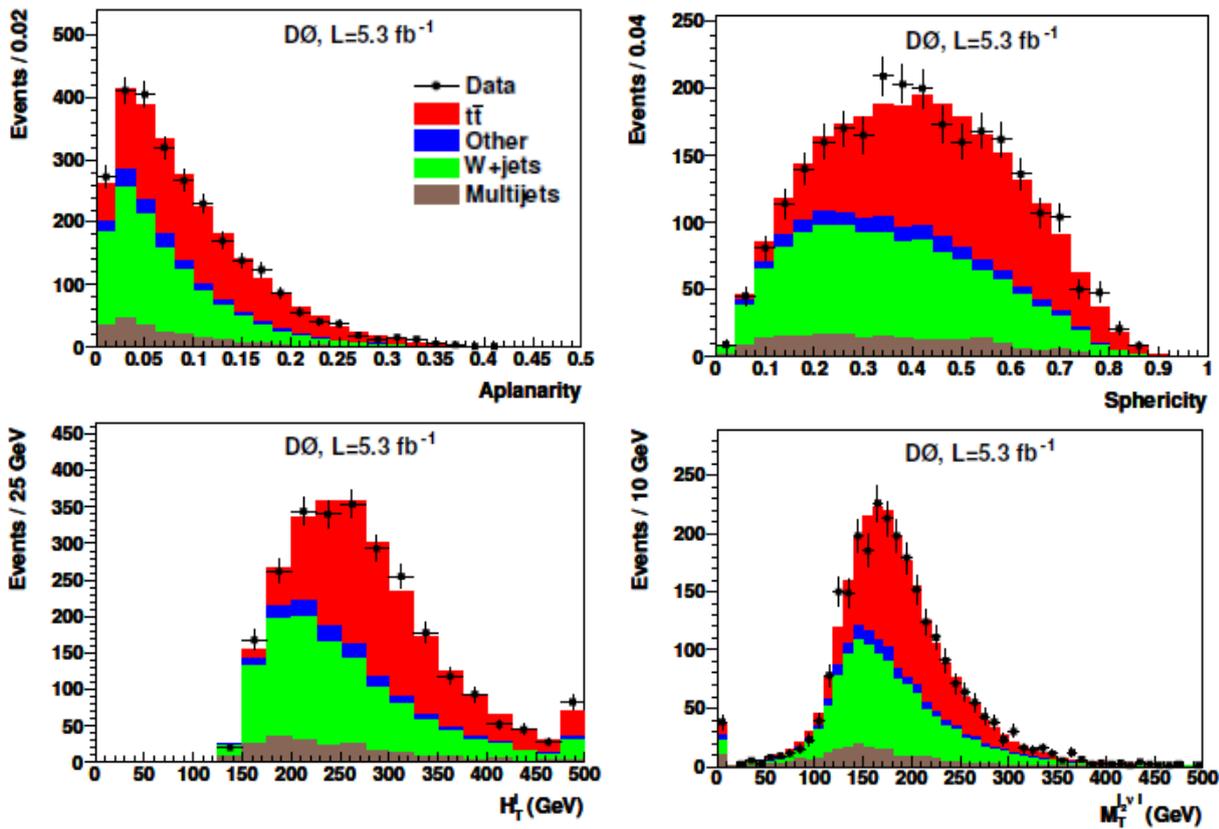

► Select events with:

- Isolated e or μ with $p_T > 20$ GeV
- Missing energy > 20 GeV
- 2 or more jets with $p_T > 20$ GeV
- Leading jet $p_T > 40$ GeV
- Other clean-up cuts
- 0, 1, or 2 b-tagged jets

e+mu, ≥ 4 jets, ≥ 1 b-tag	
W+jets	131 ± 13
Multijet	31 ± 4
Z+jets	12 ± 2
Other	19 ± 1
$t\bar{t}$	877 ± 45
Total	1066 ± 38
Observed	1060

0 b-tags: kinematic variables discriminant

Combined method (0,1,2 b-tags)

- ▶ Combine non tagged and b-tagged data for 3 and 4 jets
- ▶ Where S:B is large, just count the signal events
- ▶ Production cross section ($\sigma_{t\bar{t}}$) is proportional to the number of data-background events

	0 b-tag	1 b-tag	2 b-tags
3 jets	discr.	discr.	count
4 jets		count	count

$$\sigma_{t\bar{t}} = \frac{N_{\text{data}} - N_{\text{bkg}}}{\epsilon \cdot L}$$

$$\sigma_{t\bar{t}} = 7.8^{+0.8}_{-0.6} \text{ (stat+sys) pb}$$

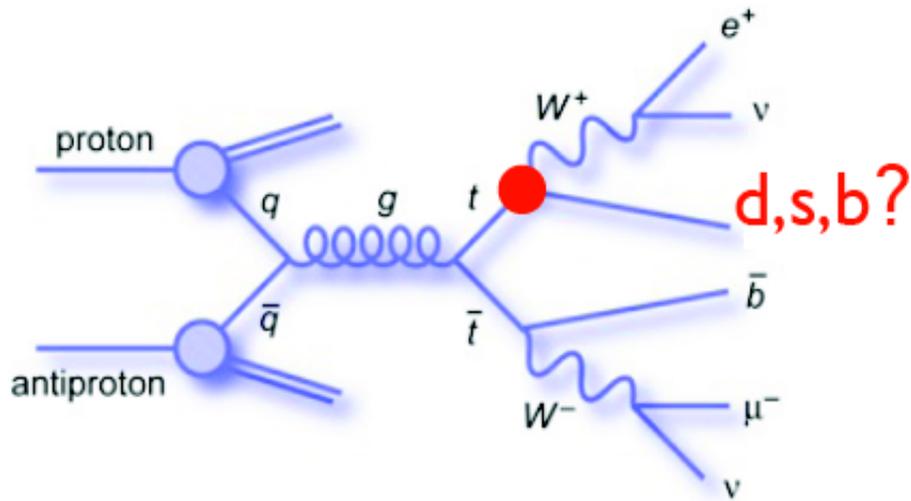

8-10% relative uncertainty

Expected in SM: $7.5^{+0.5}_{-0.7}$ pb at $m_t = 172.5$ GeV

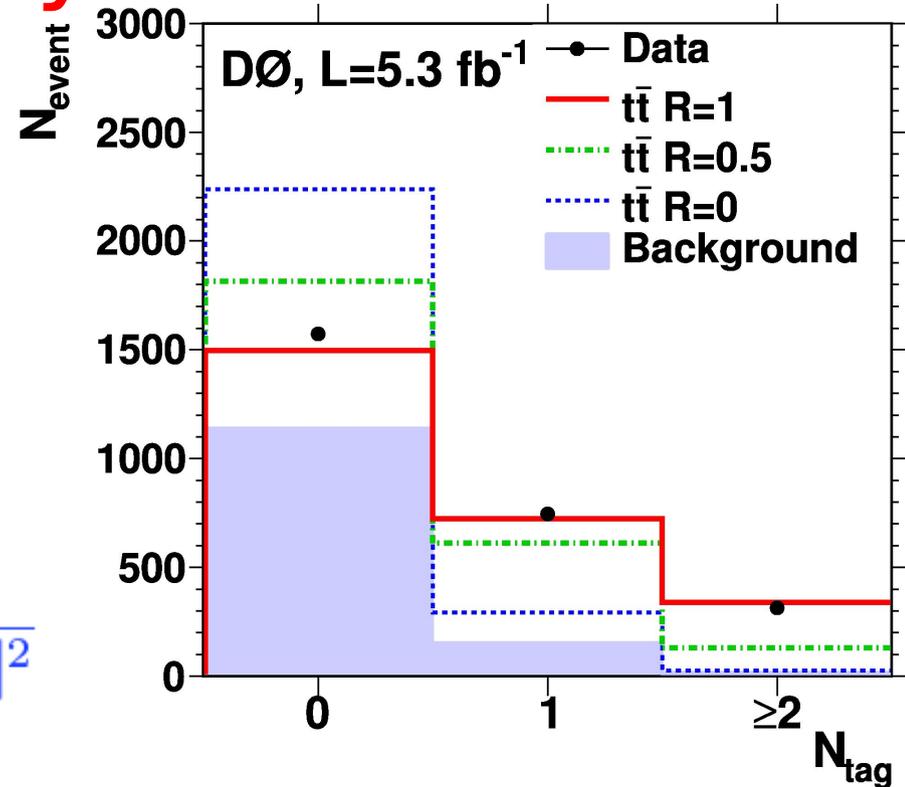

- ▶ Result is systematics limited
- ▶ Main systematic uncertainties: luminosity determination and b-tagging efficiency

Top quark decay: $t \rightarrow Wb$

$$R = \frac{BR(t \rightarrow Wb)}{BR(t \rightarrow Wq)} = \frac{|V_{tb}|^2}{|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2}$$

► In the SM, $R=1$. $R<1$ could indicate new physics (additional quarks)

► Drop assumption of $R=1$ in $\sigma(\ell+\text{jets})$ analysis

• Changes the predicted fraction of events with 0, 1 and 2 b-tags

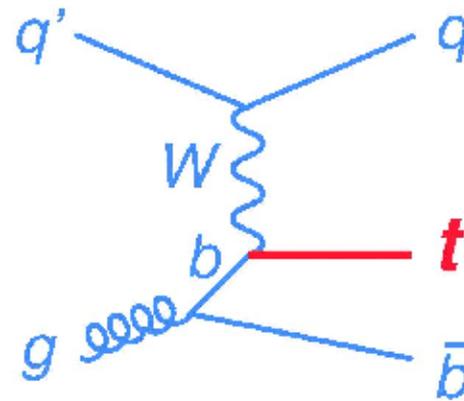

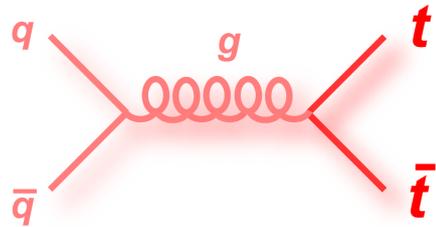

$$N_{0,1,2}(R, \sigma_{t\bar{t}}) = \left[R^2 \varepsilon_{0,1,2}^{bb} + 2R(1-R) \varepsilon_{0,1,2}^{bl} + (1-R)^2 \varepsilon_{0,1,2}^{ll} \right] \sigma_{t\bar{t}} B^2(t \rightarrow Wq) L$$

► Measure simultaneously with the $\ell+\text{jets}$ cross section

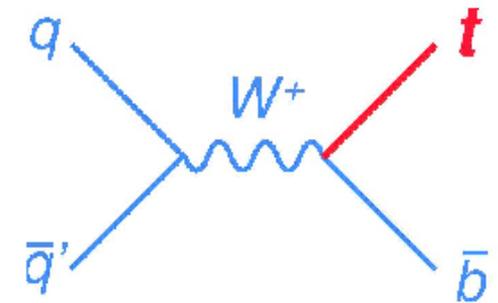

$$\sigma_{t\bar{t}} = 7.9^{+0.8}_{-0.7} \text{ (stat+sys) pb}$$

$$R = 0.95 \pm 0.07$$

Another way of producing t quarks

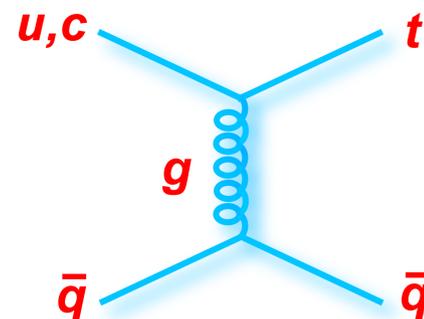

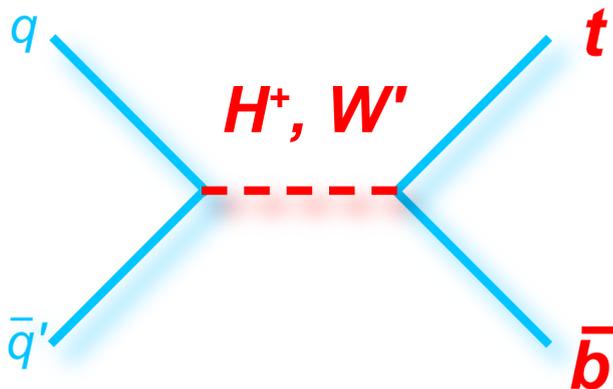

t-channel
 $\sigma = 2.1 \pm 0.1 \text{ pb}$

s-channel
 $\sigma = 1.1 \pm 0.1 \text{ pb}$

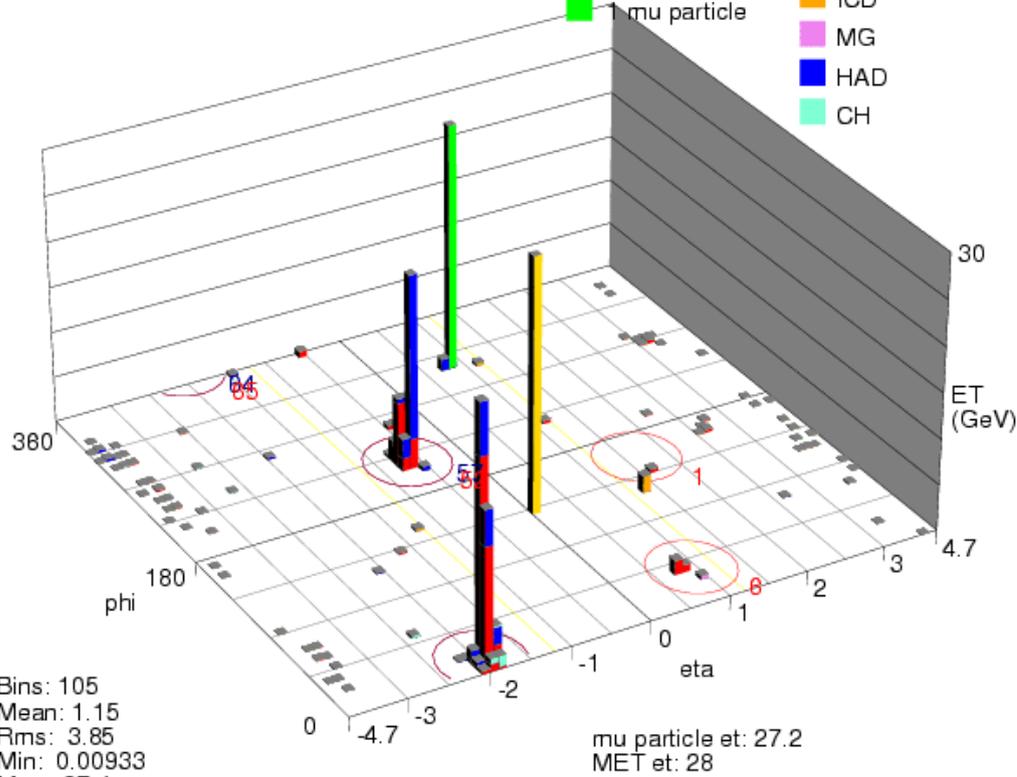

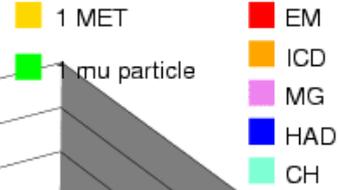

- ▶ Electroweak production of single top quarks
- ▶ This mode was only discovered in 2009!
- ▶ Can measure W-t-b coupling directly at production
- ▶ Sensitive to new physics:

A candidate event

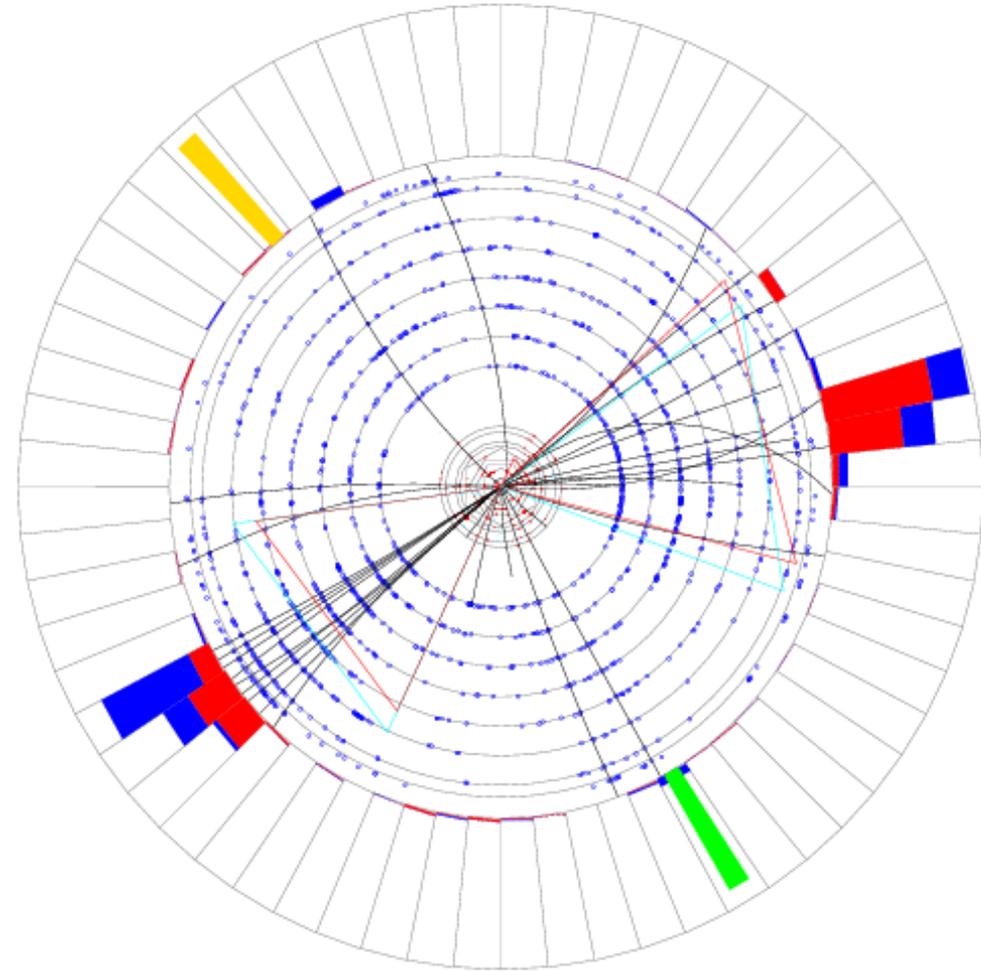

Run 177034 Evt 10482925

Triggers:

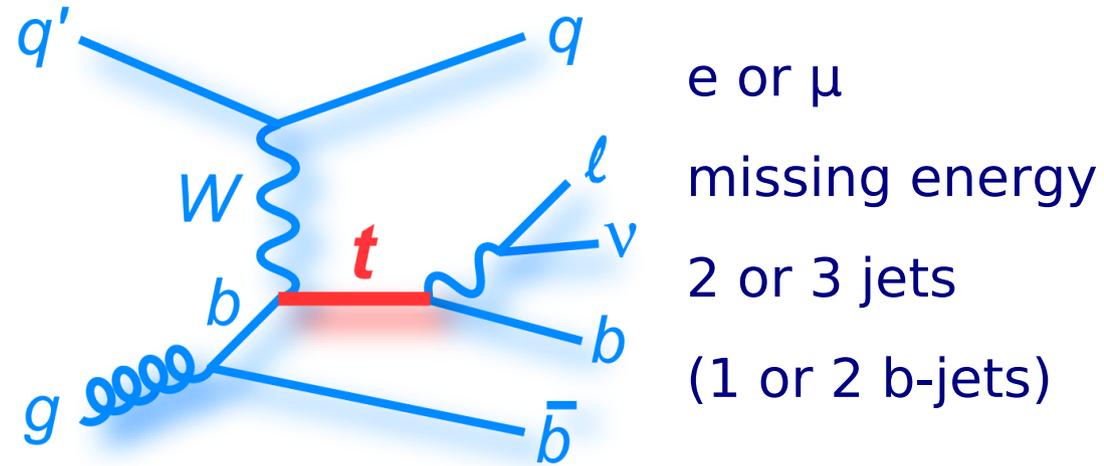

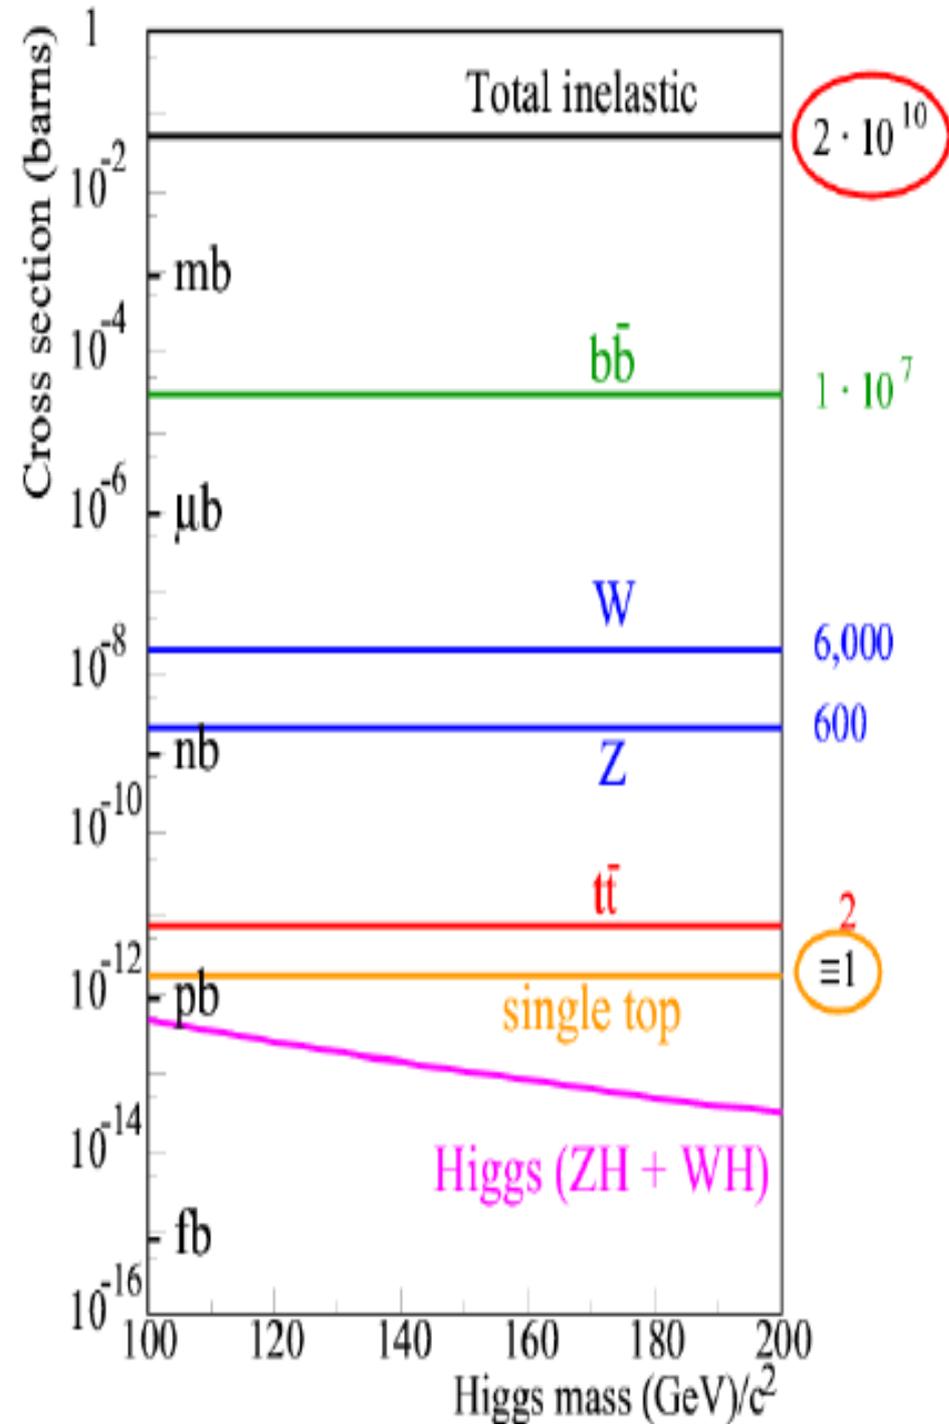

Bins: 105
 Mean: 1.15
 Rms: 3.85
 Min: 0.00933
 Max: 27.4

mu particle et: 27.2
 MET et: 28

- $M_T(\ell, \nu) = 82 \text{ GeV}$
- $M(\ell, \nu, b) = 177 \text{ GeV}$
- $Qx\eta = 1.88$

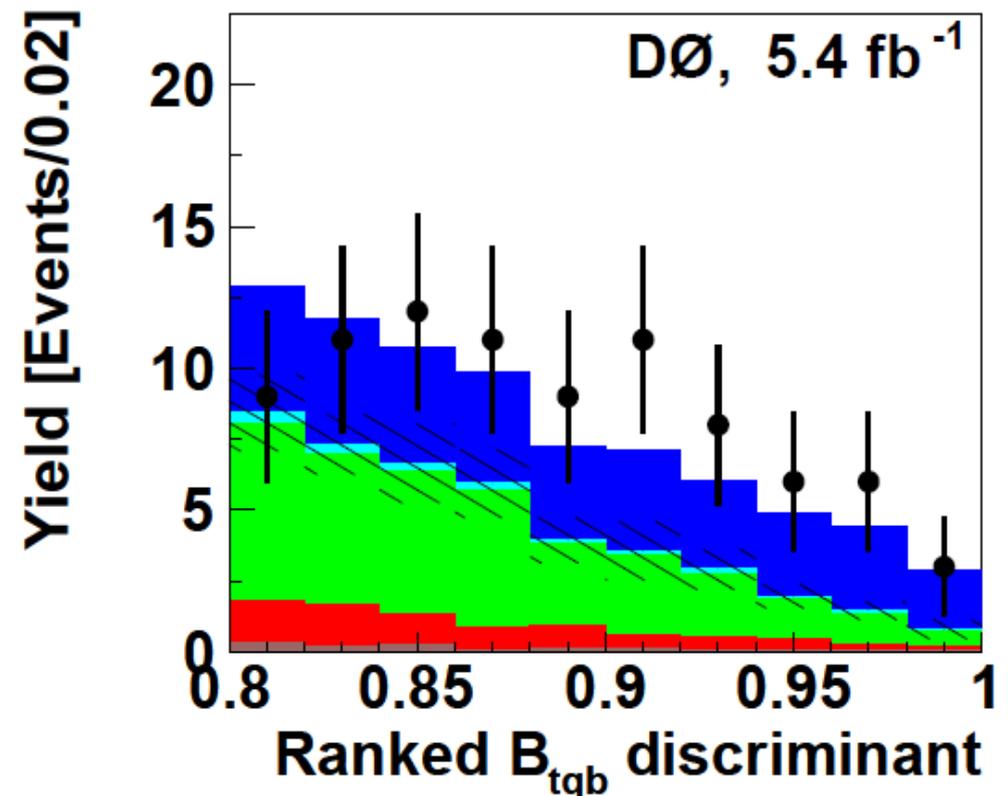

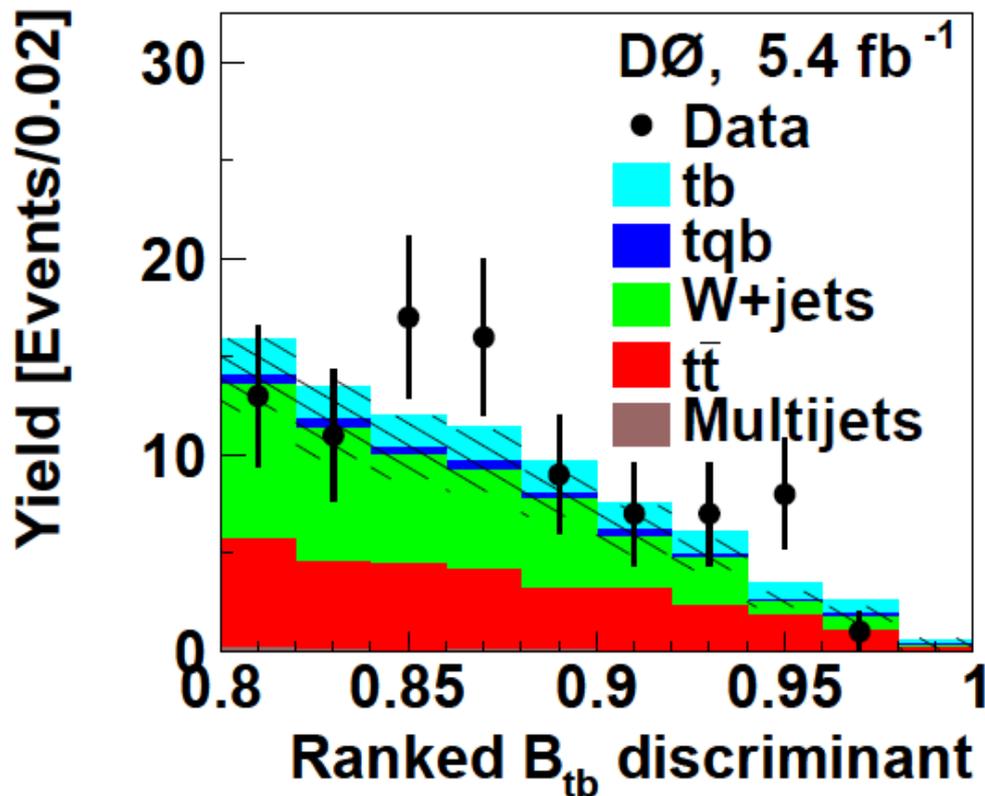

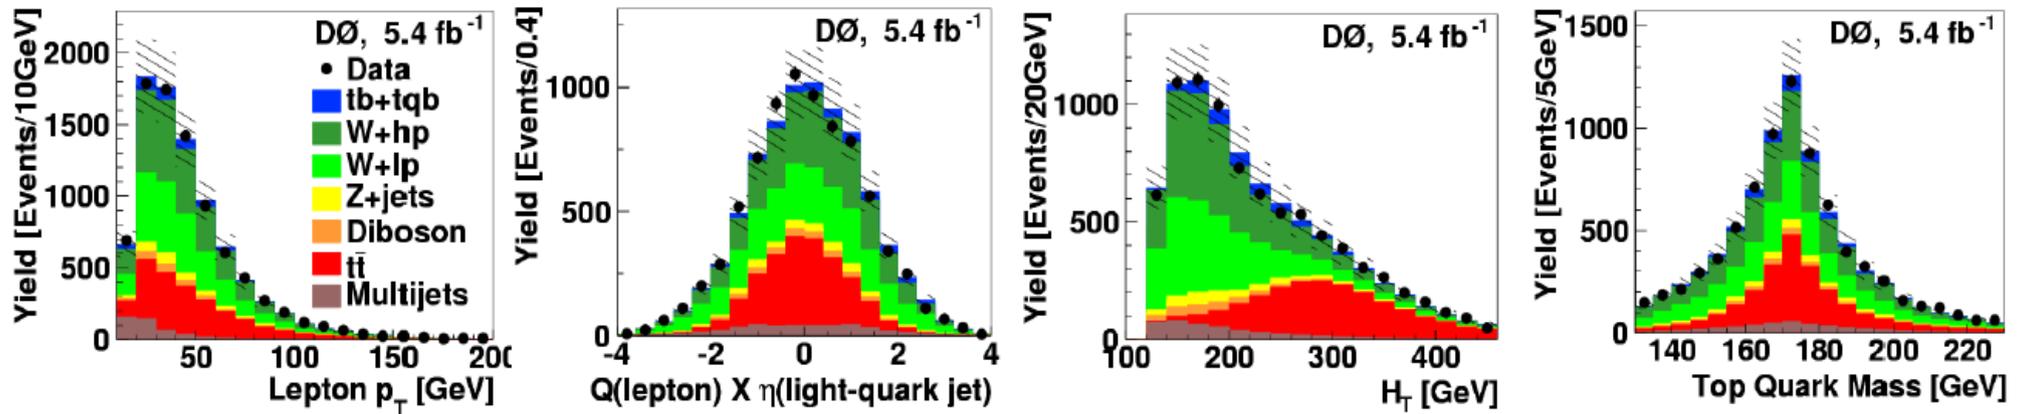

A challenging measurement

e or μ , 2,3,4 jets, ≥ 1 b-tags	
t-channel	239 ± 28
s-channel	160 ± 27
W+jets	4943 ± 598
$t\bar{t}$	2124 ± 383
Z+jets, diboson	576 ± 113
Multijets	451 ± 56
Total	8492 ± 987
Observed	8471

► Simple counting experiment cannot extract signal from huge background

Combine several machine learning methods

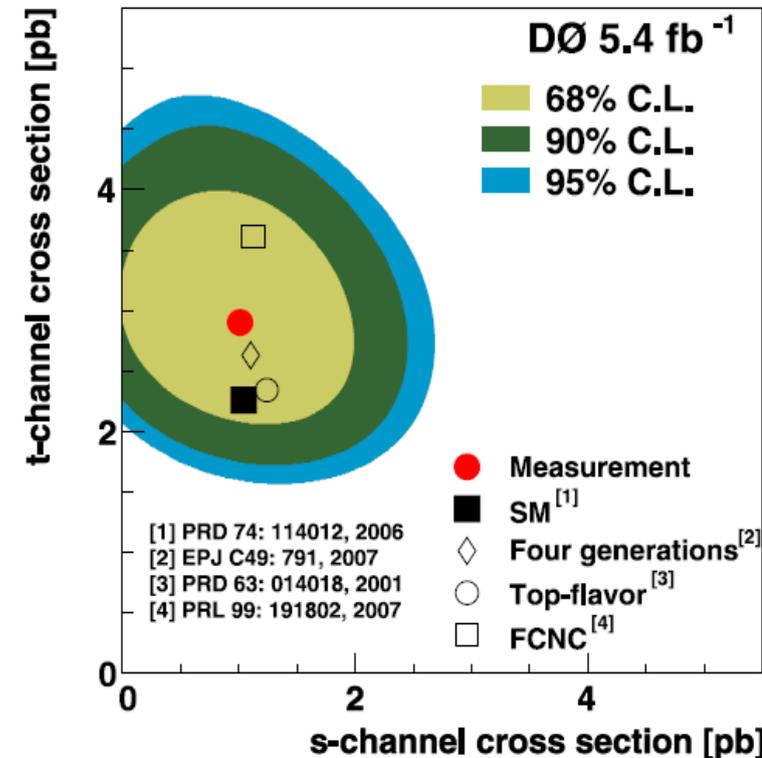

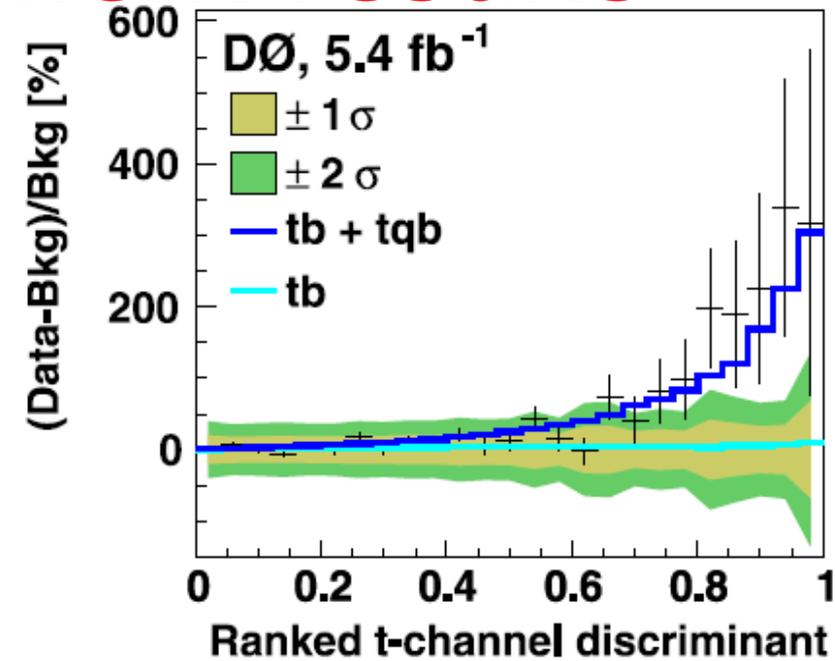

Single top measurement results

	t-channel	s-channel
Measured σ	2.9 ± 0.6 pb	1.0 ± 0.6 pb
SM expected σ	2.3 ± 0.1 pb	1.04 ± 0.04 pb
p-value	5.5 std. dev.	-

- ▶ t-channel can now be measured on its own, independently of s-channel
- ▶ Does not assume SM for s-channel
- ▶ Obtain 20% precision on t-channel measurement
- ▶ Translate tb+ tqb measurement in constrain on $|V_{tb}|$ without assuming 3 families:

$$|V_{tb} f_L| = 1.02 \pm 0.11$$

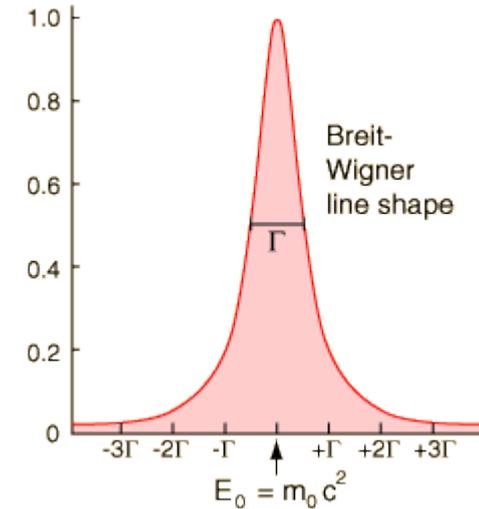

Top decay lifetime

▶ The decay lifetime (half-life) tends to decrease with larger mass

- $\tau(\mu \rightarrow e^- \bar{\nu}_e \nu_\mu) = 2 \cdot 10^{-6} \text{ s}$ ($m_\mu = 0.1 \text{ GeV}$)
- $\tau(\bar{u}b \rightarrow c+X) = 1 \cdot 10^{-12} \text{ s}$ ($m_B = 5 \text{ GeV}$)
- SM expected $\tau(t \rightarrow Wb) \sim 10^{-25} \text{ s}$ ($m_t = 173 \text{ GeV}$)

▶ The decay width is easier to measure: $\Gamma = \hbar/\tau$

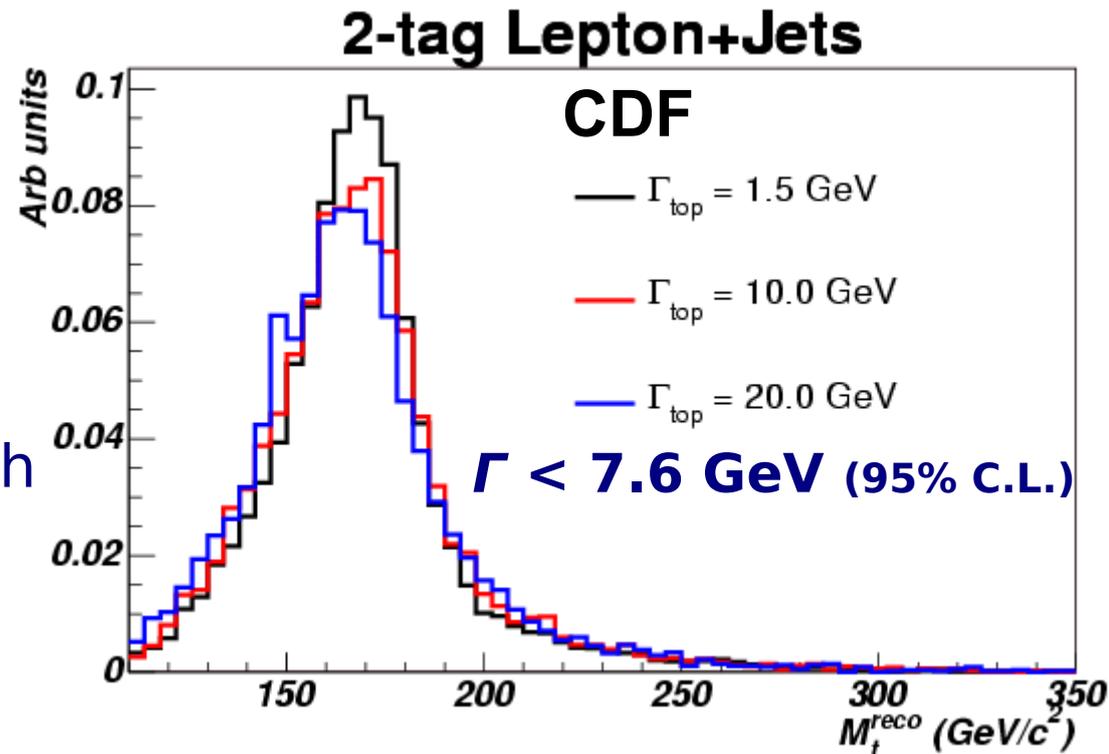

▶ Γ is the spread in measured energy due to Heisenberg's unc. principle

▶ Direct measurement is independent of assumptions, but is limited by experimental resolution

▶ For top quark:
exp. resolution $>$ natural width

$$\Gamma_t = 1.3 \text{ GeV}$$

Indirect measurement

- Idea: use the partial decay width and decay fraction

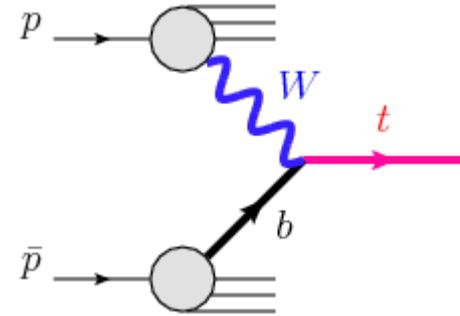

$$\Gamma_t = \frac{\Gamma(t \rightarrow Wb)}{B(t \rightarrow Wb)}$$

$$\sigma(tqb) \frac{\Gamma(t \rightarrow Wb)_{SM}}{\sigma(tqb)_{SM}}$$

single top t-channel cross section:
 $\sigma(tqb)$ is proportional to $\Gamma(t \rightarrow Wb)$

$$R = \frac{B(t \rightarrow Wb)}{B(t \rightarrow Wq)}$$

ratio of decay branching fractions assuming $B(t \rightarrow Wq) = 1$

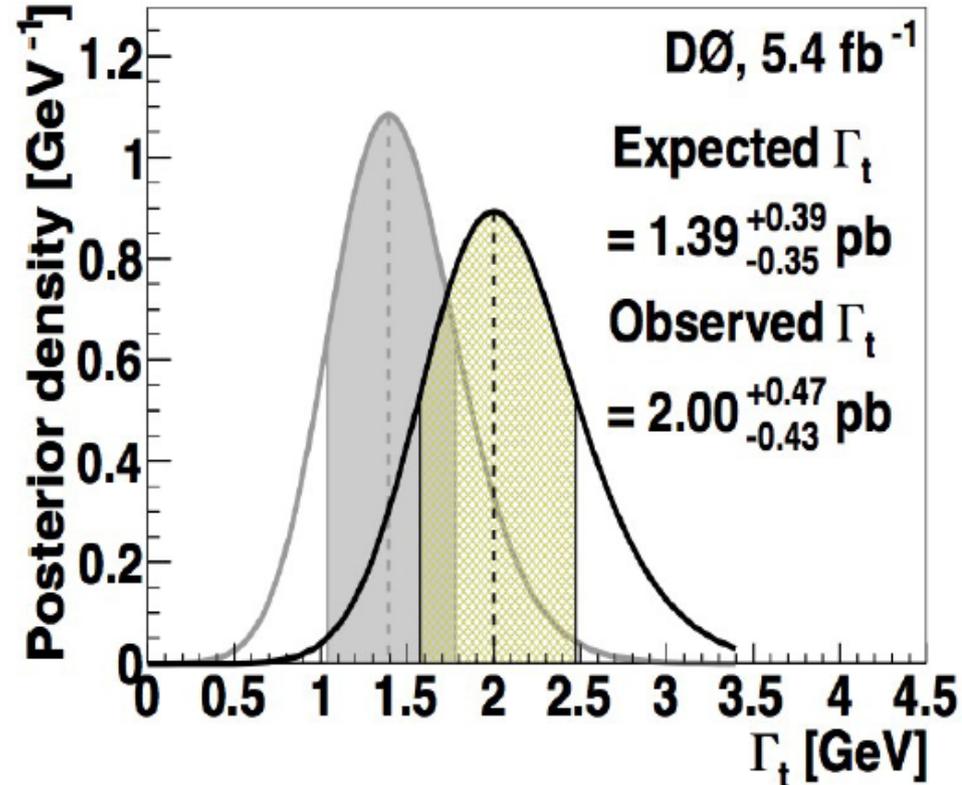

- This result assumes that the production (in t-channel) and decay have the same properties
- New particles like b' could modify this width

$$\Gamma_t = 2.0^{+0.5}_{-0.4} \text{ GeV}$$

$$\tau_t = (3.3^{+0.9}_{-0.6}) 10^{-25} \text{ s}$$

$$|V_{tb'}| < 0.59$$

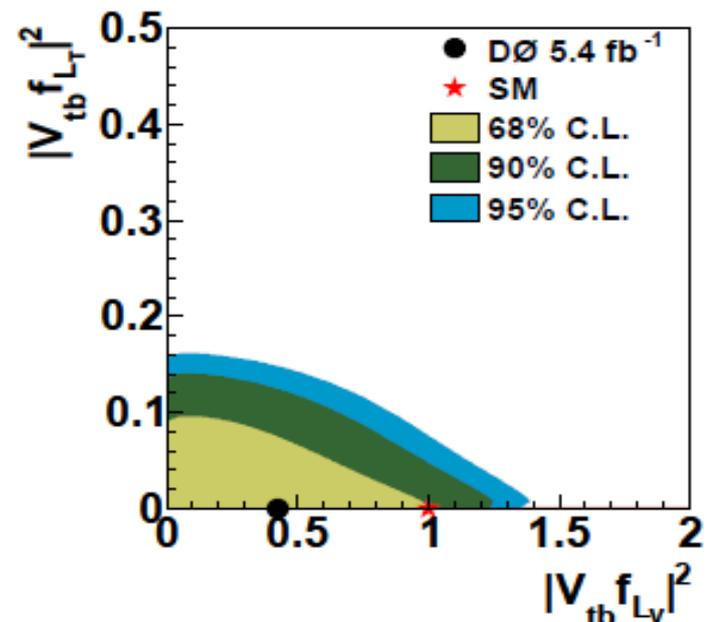

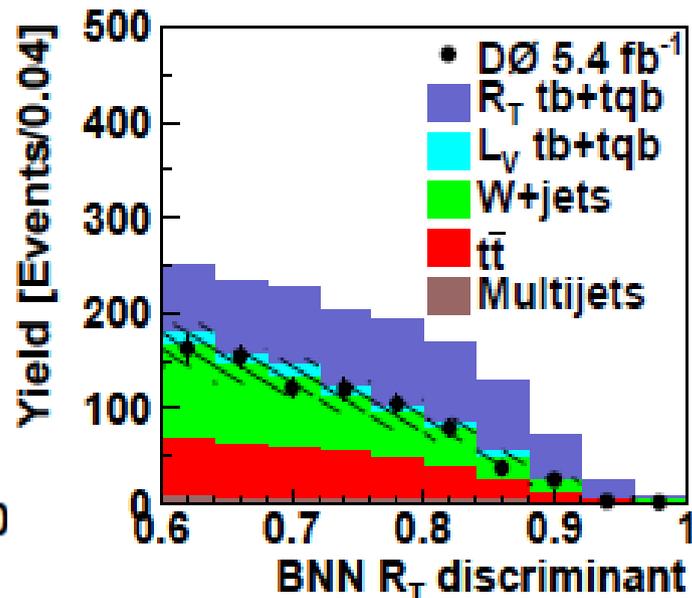

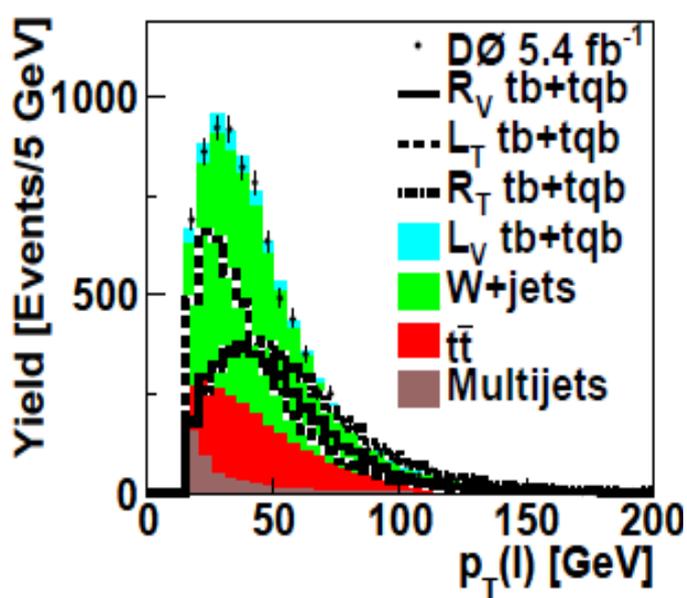

Search for new physics

- ▶ Generic lagrangian for W-t-b interaction:

$$\mathcal{L} = \frac{g}{\sqrt{2}} \bar{b} \gamma^\mu (L_V P_L + R_V P_R) t W_\mu^- + \frac{g}{\sqrt{2}} \bar{b} \frac{i\sigma^{\mu\nu} q_\nu}{M_W} (L_T P_L + R_T P_R) t W_\mu^-$$

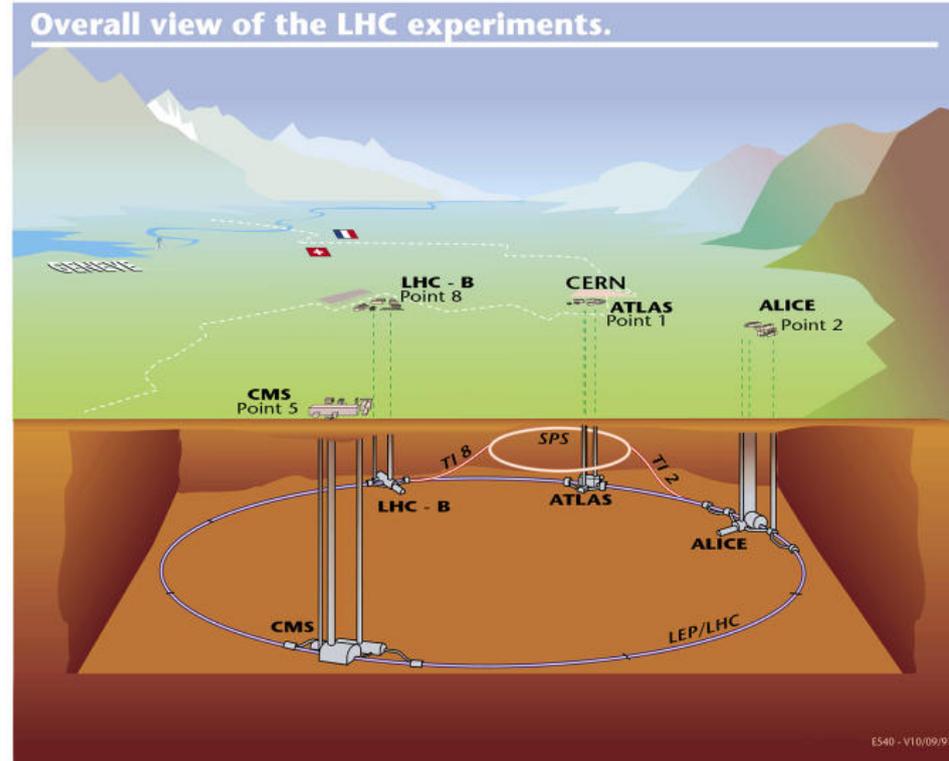

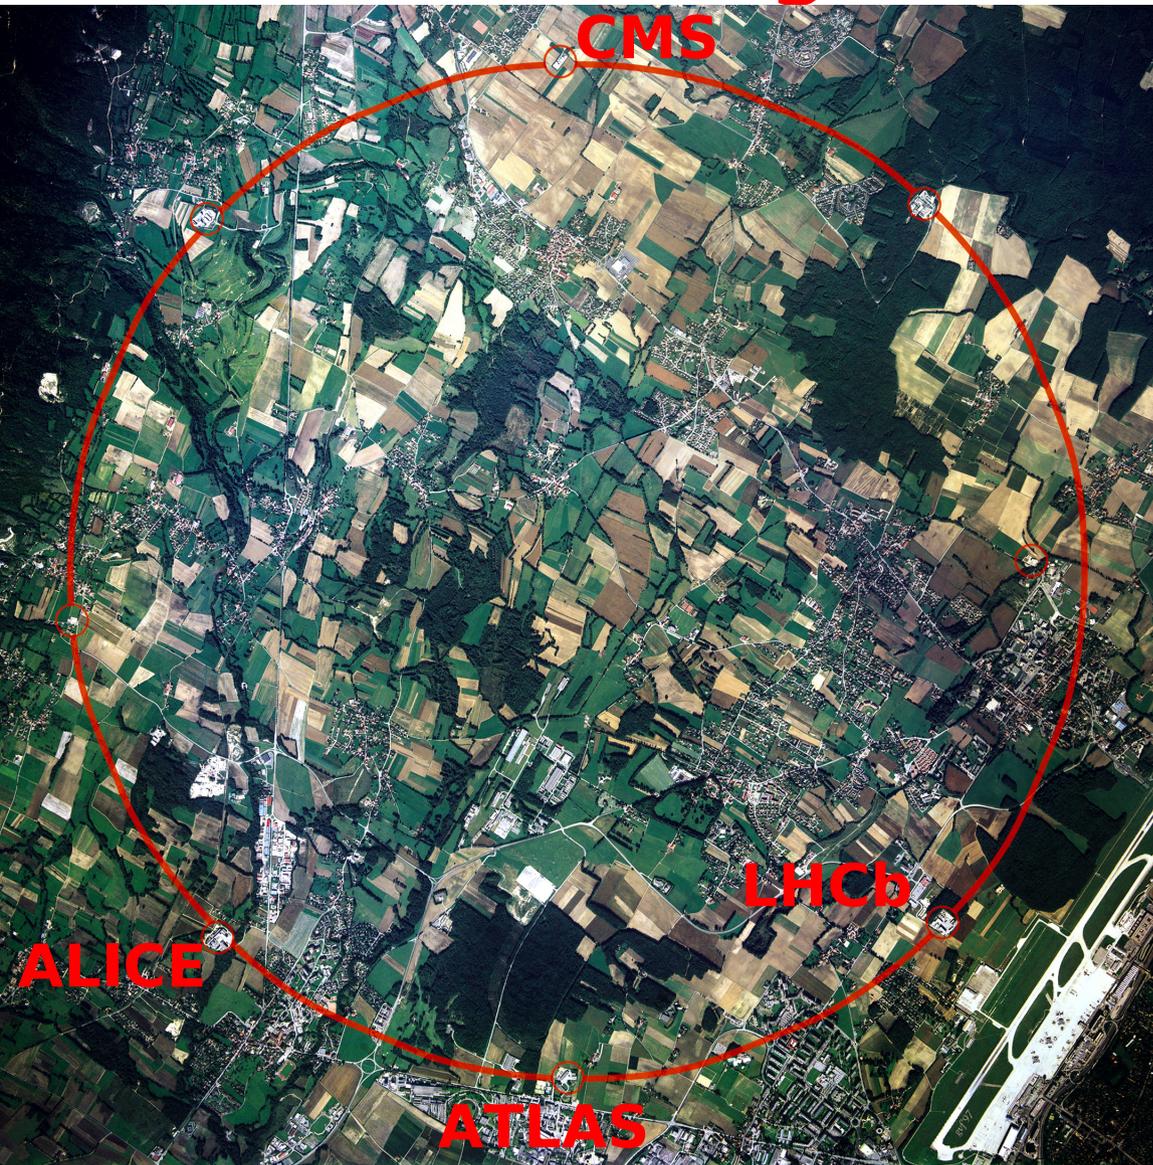

- ▶ SM: only left-handed vector couplings L_V are allowed ($R_V=L_T=R_T=0$)
- ▶ Anomalous top quark couplings would change the kinematics of single top production
- ▶ No deviation is seen in the data
- ▶ We exclude one new coupling at a time, assuming the the other two are negligible: ($R_V=R_T=0$) , ($L_T=R_T=0$) , ($R_V=L_T=0$)

Top quark Tevatron scorecard

Property	Measurement	SM Prediction	Luminosity (fb ⁻¹)
$\sigma_{t\bar{t}}$ (for $M_t = 172.5$ GeV)	CDF: $7.5 \pm 0.31(\text{stat}) \pm 0.34(\text{syst}) \pm 0.15(\text{theory})$ pb D0: $7.56_{-0.56}^{+0.63}$ (stat + syst + lumi) pb	$7.46_{-0.67}^{+0.48}$ pb	up to 4.6 5.6

The Large Hadron Collider

- ▶ p-p collider at $\sqrt{s}=7$ TeV
- ▶ 26 km long, 100m underground
- ▶ Delivered luminosity: 5.5 fb^{-1}
- ▶ Peak luminosity: $3.5 \cdot 10^{33} \text{ cm}^2\text{s}^{-1}$
- ▶ Crossing rate: 40 MHz
- ▶ Rare processes: 1 in 10^{13}

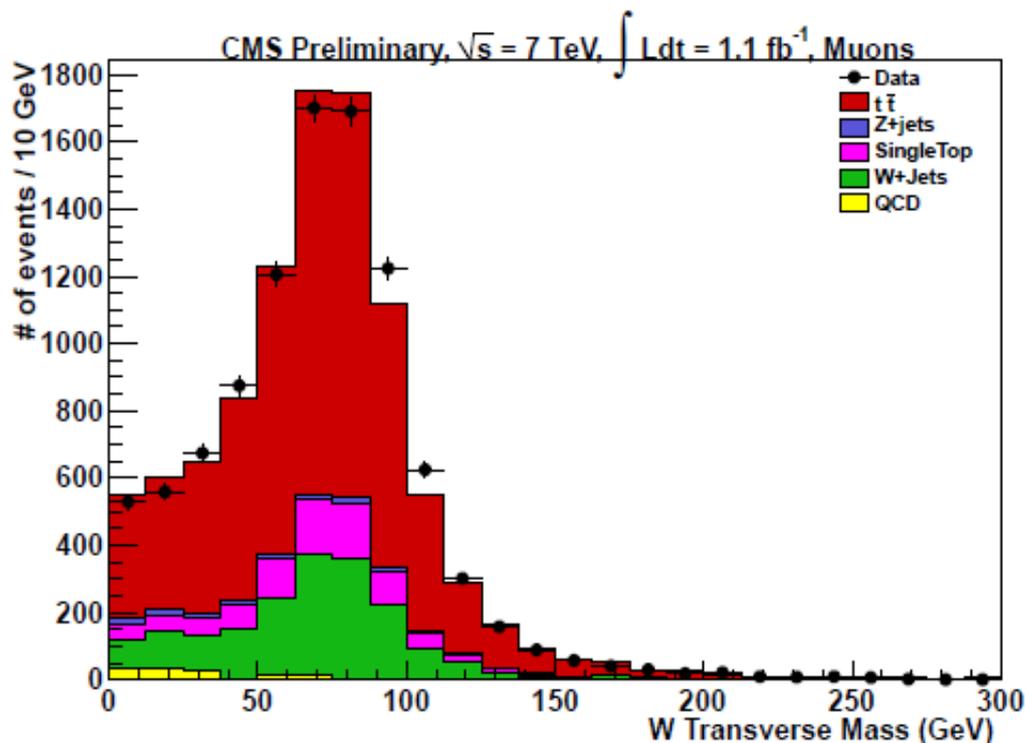

1 fb^{-1} of LHC data produces 24 times more $t\bar{t}$ pairs than 1 fb^{-1} of TeV data
18,000 top pairs in one fill of 16 hours!

Diameter: 15 m
Length: 21 m
Weight: 12500 tons
Solenoid: 4 T, 12-m long

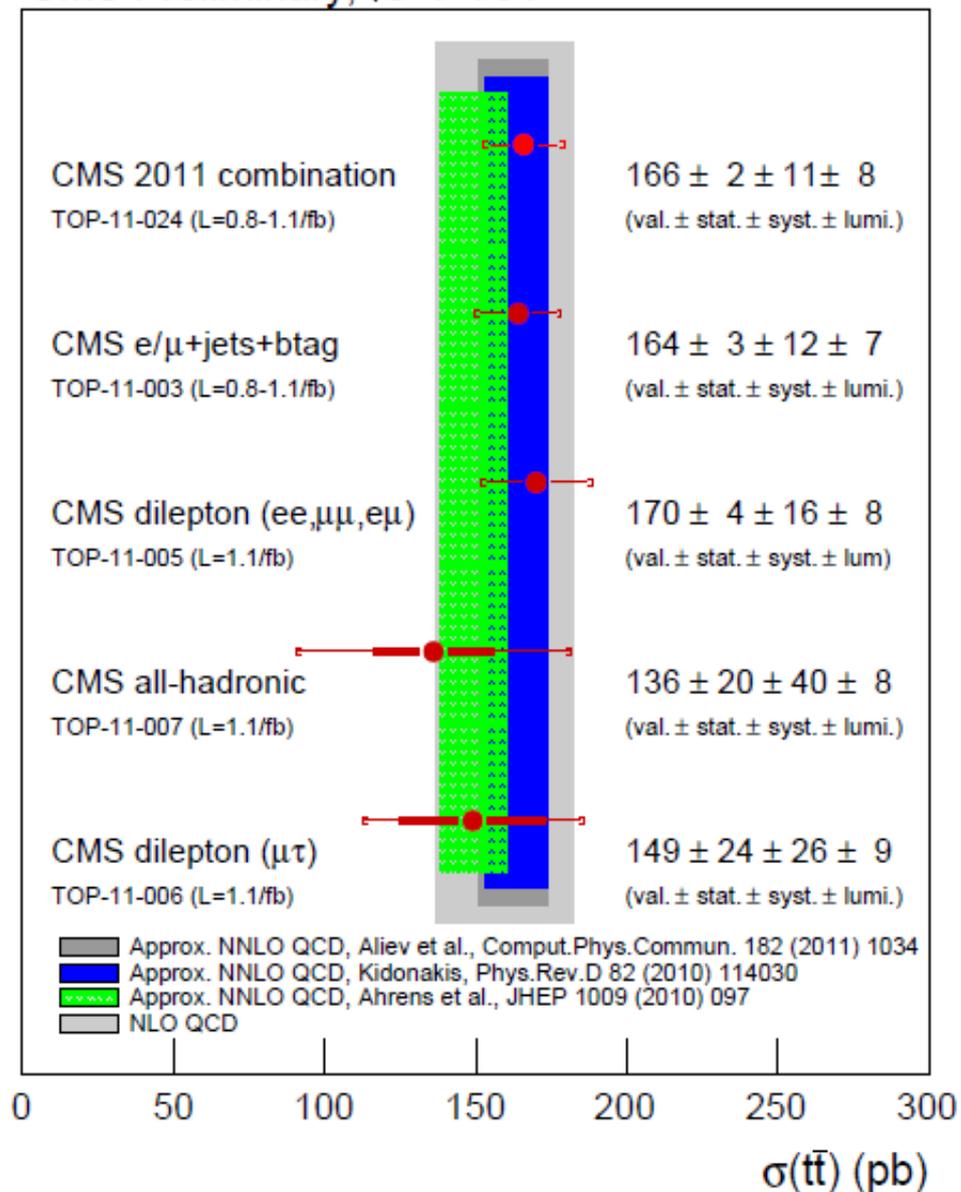

$t\bar{t}$ pairs results from LHC

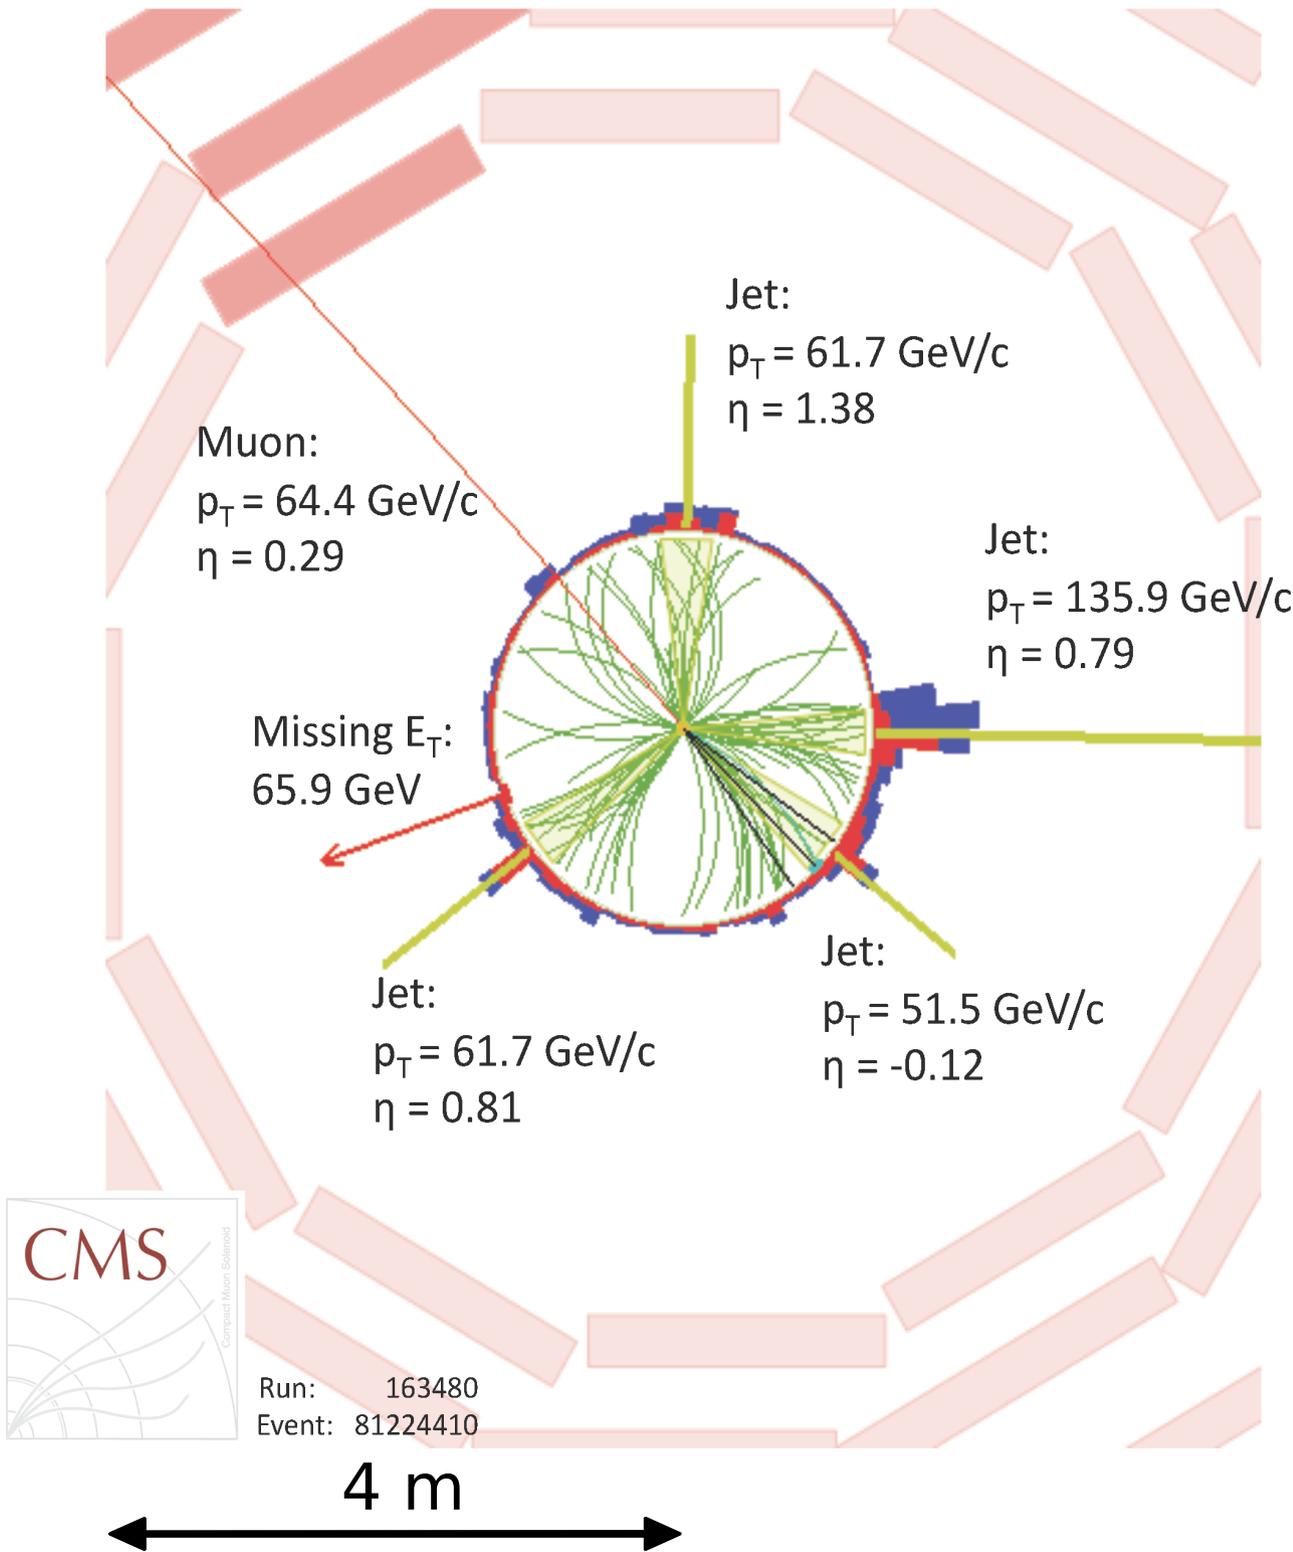

- ▶ Huge production rate: from 7 pb to 165 pb
- ▶ Latest CMS analysis has $\sim 13,000$ top pairs candidates with 1fb^{-1}
- ▶ Achieves 8% relative uncertainty

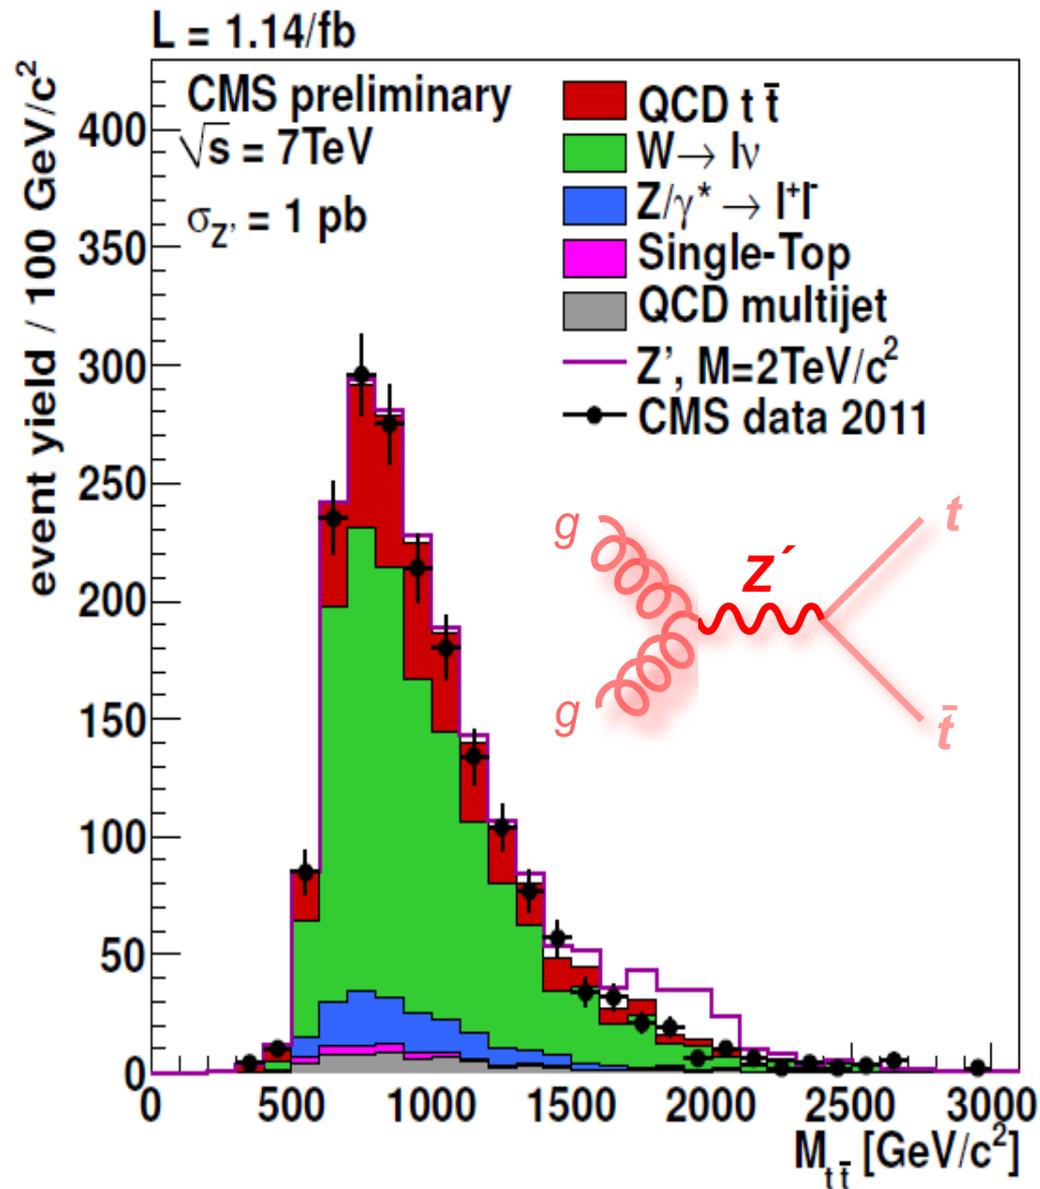

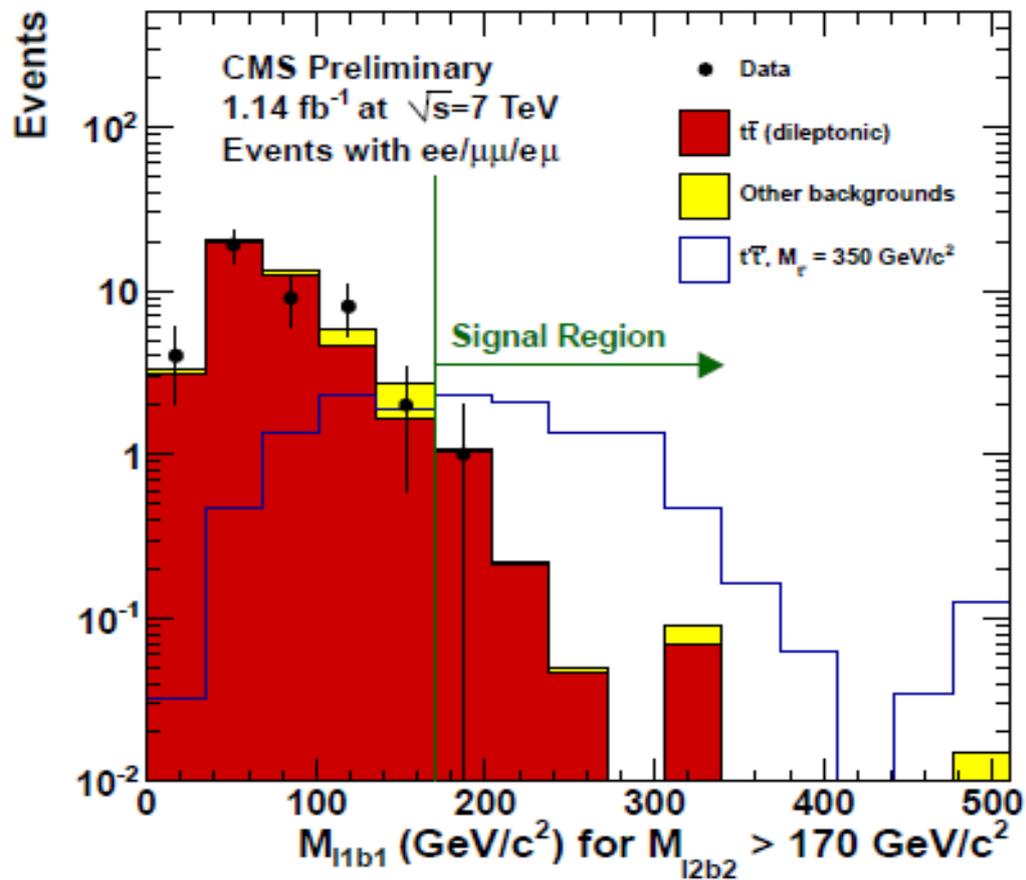

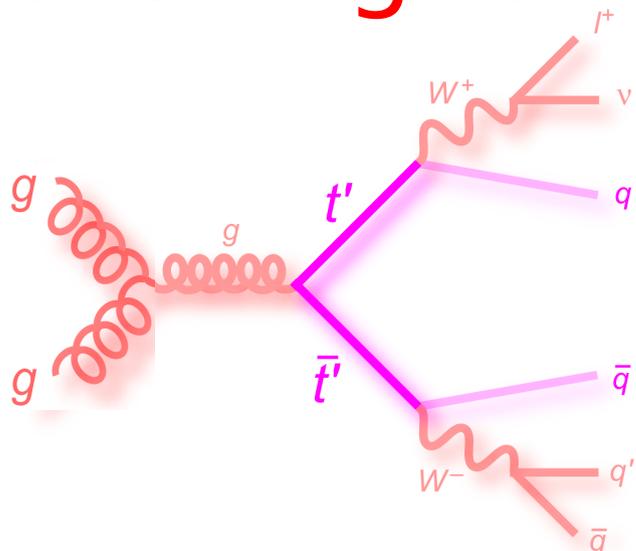

Now moving on to expand the measurements of properties and searches for new physics

CMS Preliminary, $\sqrt{s} = 7\text{ TeV}$

Searching for heavy new particles

No sign of new physics yet!

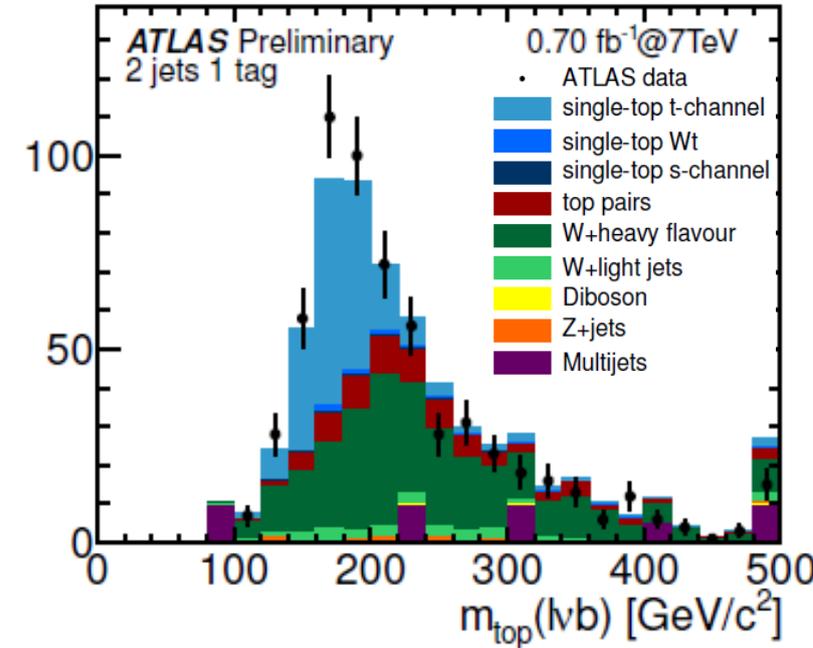

Single top results from LHC

- It is possible to measure the t-channel cross section with simple cuts

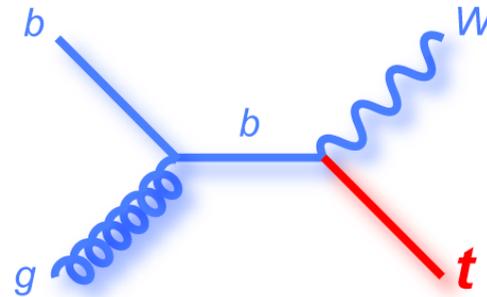

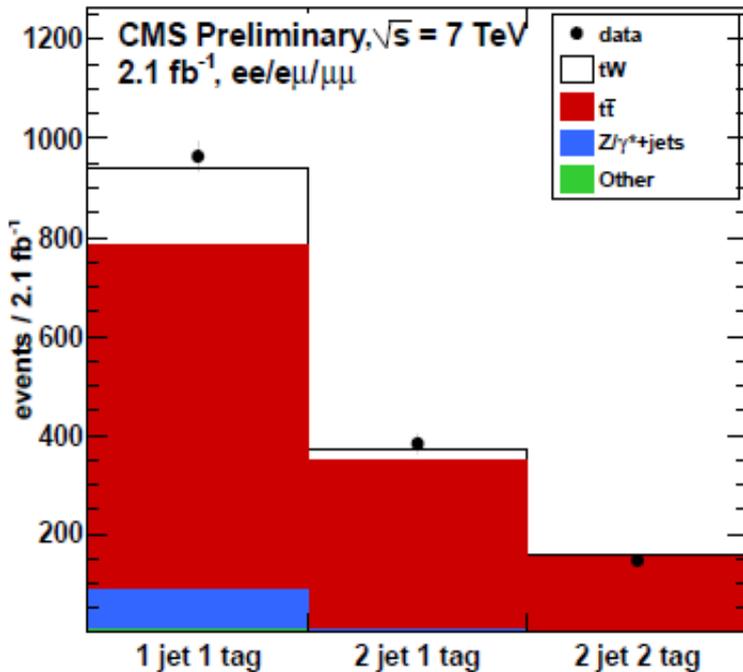

$$\sigma_{tqb} = 90^{+31}_{-20} \text{ pb} \quad 7.6 \text{ std. dev.}$$

Expected in SM: 64 ± 3 pb at $m_t = 173$ GeV

Candidate Events

- New channel of production opens up:
 $tW \rightarrow Wb \quad W \rightarrow l\nu b \quad l\nu$

$$\sigma_{tW} = 22^{+9}_{-7} \text{ pb} \quad 2.7 \text{ std. dev.}$$

Expected in SM: 16 ± 1 pb at $m_t = 173$ GeV

$M(ee)$:
64.4 GeV/c²

Electron
 $p_T=30.5$ GeV/c
 $\eta= -1.37$

Electron
 $p_T=46.2$ GeV/c
 $\eta= -1.38$

Missing E_T :
134.5 GeV

Jet
 $p_T=118.0$ GeV/c
 $\eta= 0.09$

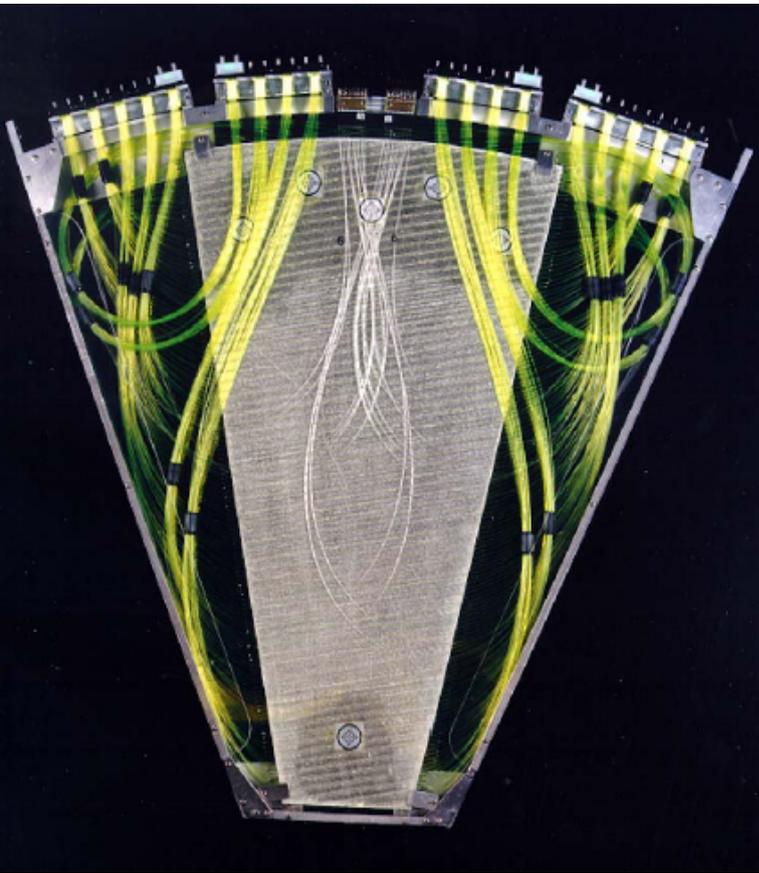

Run: 170876
Event: 306699209

Conclusions

- ▶ After 16 years the Tevatron has studied extensively the top quark production and its properties
 - It behaves as the SM predicts
- ▶ This remains an active and exciting topic
 - Some deviations from the SM are seen
 - Will publish results with 2 times larger dataset next year
 - Pushing the precision of theoretical calculations
 - Will focus on studies that cannot be done at LHC
- ▶ The top quark discovery and its full study will remain as the main legacy from the Tevatron
- ▶ The LHC has re-established the SM at 7 TeV
 - It is a top factory: precision will be much higher soon
- ▶ No sign of new physics yet
 - Very important limits on models beyond the SM
- ▶ Will collect lots of data next year and then 14 TeV in 2014!

Detectors as art

DØ forward preshower module at the Museum of Modern Art, New York

CDF Run I Silicon vertex detector at the Smithsonian museum, Washington

to courtesy of Brenna Flaugher

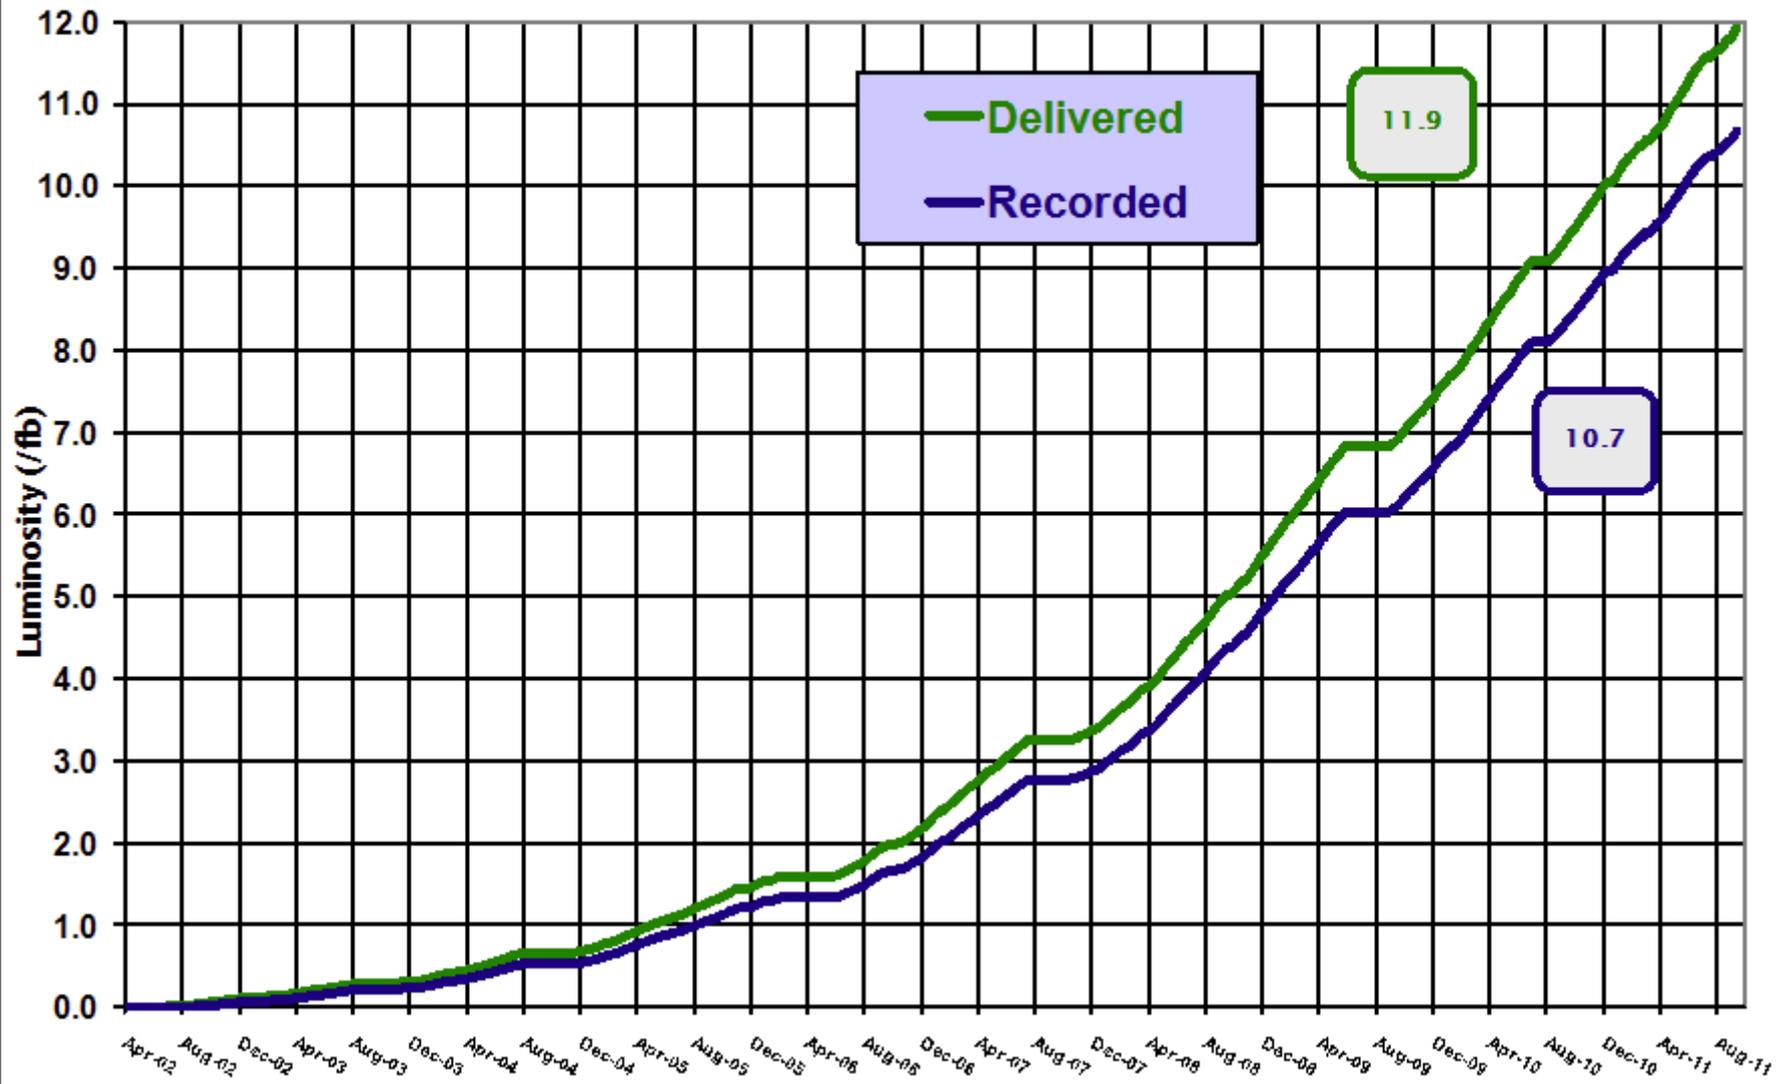

Extra slides

For more information:

Run II Integrated Luminosity

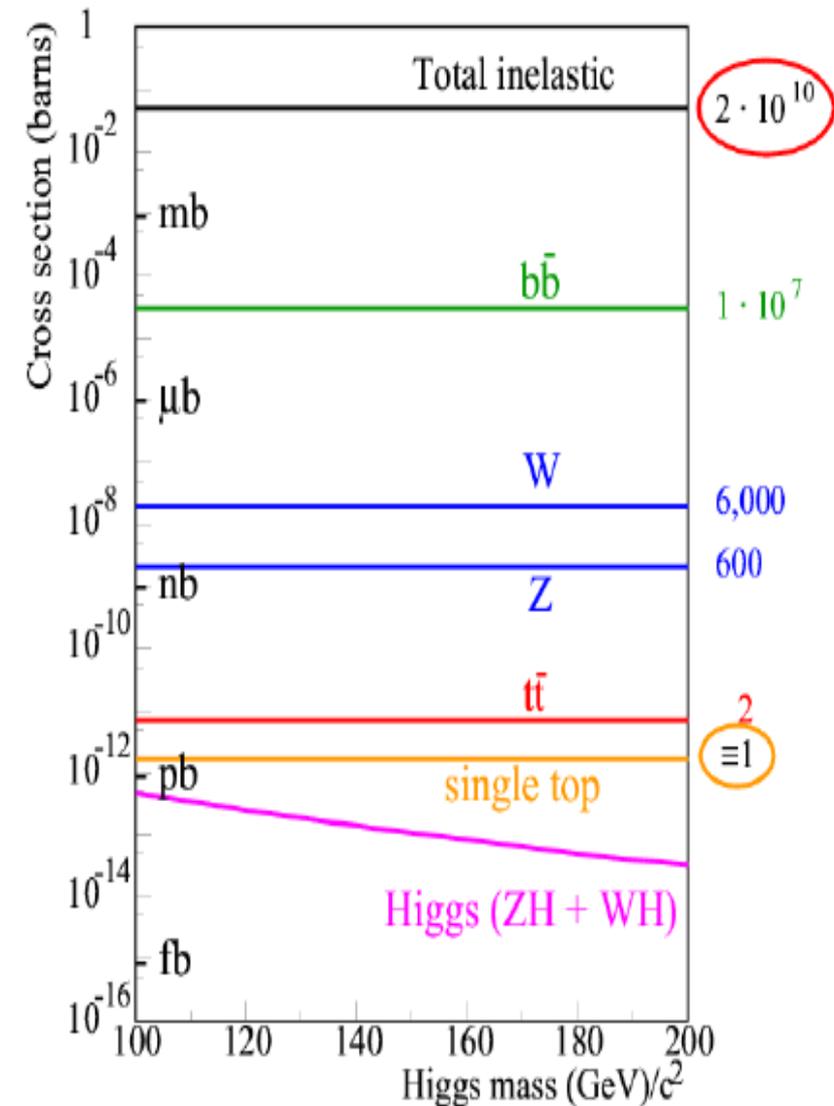

19 April 2002 - 30 September 2011

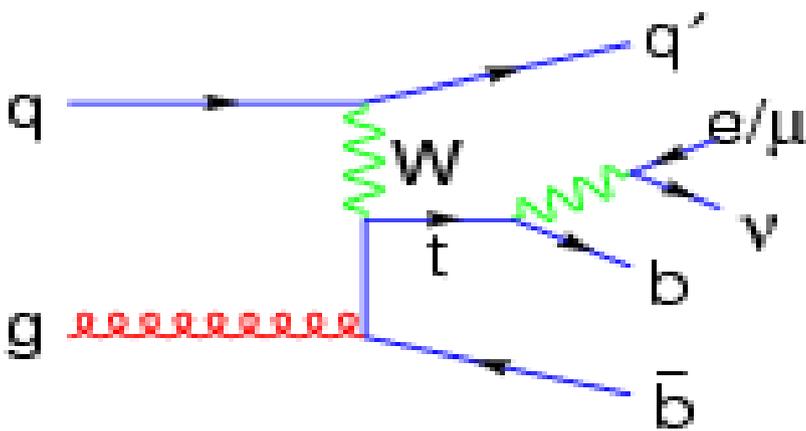

Physics at a hadron collider is like... drinking from a fire hose

- ▶ Collision rate is huge
Every 396 ns \rightarrow ~ 1.7 MHz (live crossings)
- ▶ Total cross section ~ 0.1 b
2-3 interactions per collision at $L=10^{32}$
- ▶ But W, Z, t, H are rare!
Around 20 single top events per day
- ▶ Need trigger system to select interesting events
Only store manageable size ~ 25 MB/s

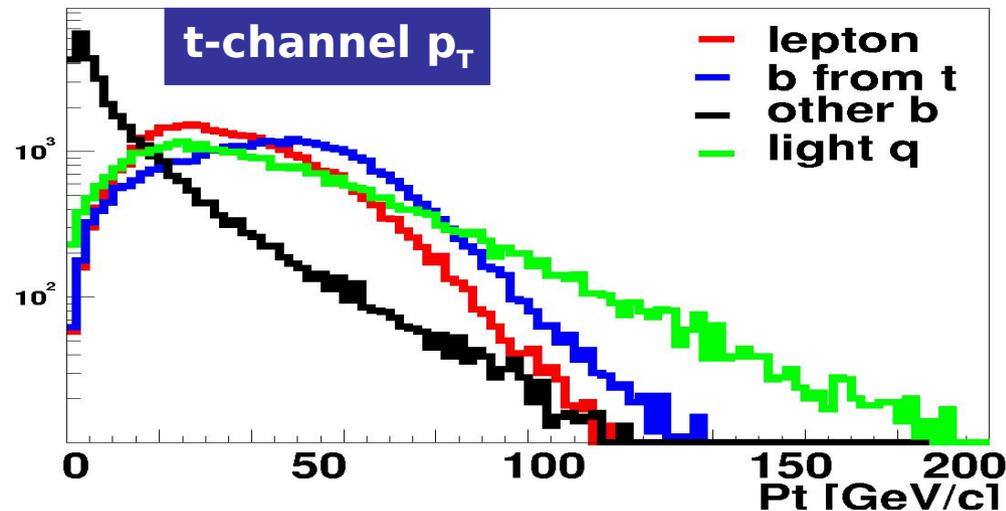

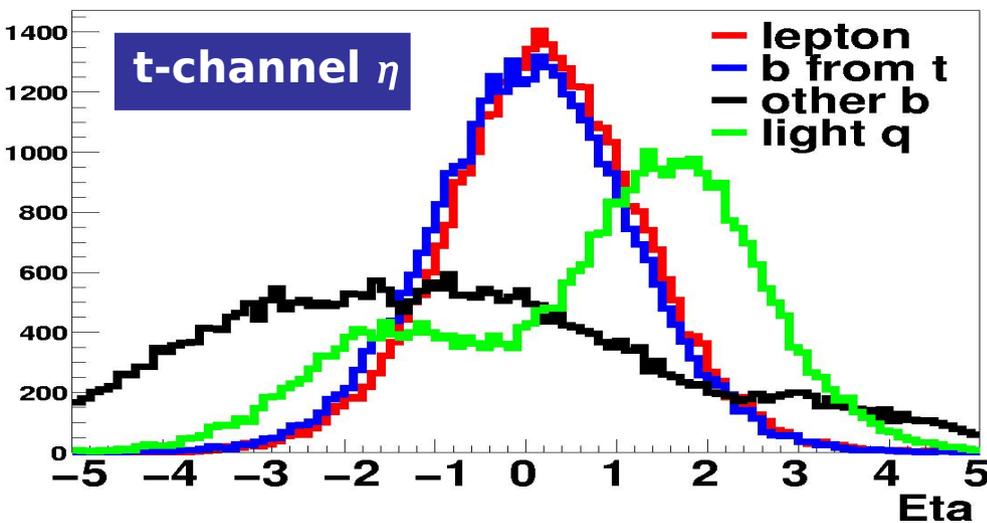

Signal selection

Signature:

- One high p_T isolated lepton (from W)
- MET (ν from W)
- One b-quark jet (from top)
- A light flavor jet and/or another b-jet

Event selection:

▶ Only one tight (no loose) lepton:

● e: $p_T > 15$ GeV and $|\eta^{\text{det}}| < 1.1$

● μ : $p_T > 18$ GeV and $|\eta^{\text{det}}| < 2.0$

▶ MET > 15 GeV

▶ 2-4 jets: $p_T > 15$ GeV and $|\eta^{\text{det}}| < 3.4$

● Leading jet: $p_T > 25$ GeV ; $|\eta^{\text{det}}| < 2.5$

● Second leading jet: $p_T > 20$ GeV

▶ One or two b-tagged jets

Preparing the way for the LHC

Studies at the Tevatron will help the LHC:

- ▶ Wbb measurement (will also help WH search) (DØ: hep-ex/0410062)
Current limit at 4.6 pb for $p_T(b) > 20\text{GeV}$
- ▶ In general, W+jets background determination techniques
tt will be main background, but large uncertainties come from W+jets
Effect of jet vetoes ($N_{\text{jet}}=2$), check other methods planned in LHC analyses
- ▶ Study charge asymmetries (Bowen, Ellis, Strassler: hep-ph/0412223)
Signal shows asymmetry in $(Q_\ell \times \eta_j, Q_\ell \times \eta_\ell)$ plane at TeV
- ▶ Study kinematics of forward jets in t-channel (WW→H at LHC)
- ▶ Even measure asymmetry in production rate (Yuan: hep-ph/9412214)
(probe CP-violation in the top sector):

$$A_t = \frac{\sigma(p\bar{p} \rightarrow tX) - \sigma(p\bar{p} \rightarrow \bar{t}X)}{\sigma(p\bar{p} \rightarrow tX) + \sigma(p\bar{p} \rightarrow \bar{t}X)}$$

TeV4LHC workshop report: 0705.3251 [hep-ph]
