Total scattering cross section of a dielectric sphere

The total power emitted by a dipole is computed by integrating the Poynting vector over any surface that encloses the dipole, like any sphere for which the radius puts it in the far field:

It doesn't matter how this dipole is made to oscillate; once it does, though, it will radiate as described, with the total power given above.

Total scattering cross section of a dielectric sphere (continued)

Suppose, instead of the dipole we started with, we have a dipole *induced* by an oscillating external electric field $E_0 \cos \omega t$ – for example, a small dielectric sphere, with radius *a* small enough to consider that there is no delay in propagation of the field across it. The dipole moment of such a sphere is $p = \frac{4\pi}{3}a^3P = \frac{4\pi}{3}a^3\chi_e E_0 \cos \omega t \equiv p_0 \cos \omega t$

Suppose furthermore that the external electric field is supplied by a plane electromagnetic wave that's passing by the cube. The power radiated by the dipole is thus traceable back to the incident wave: the cube has **scattered** some of the incident light, due to radiation by the induced dipole moment.
