

The circular aperture

Most experimental situations in optics (e.g. telescopes) have circular apertures, so the application of the Kirchhoff integral to diffraction from such apertures is of particular interest. We start with a plane wave incident normally on a circular hole with radius *a* in an otherwise opaque screen, and ask: what is the distribution of the intensity of light on a screen a distance R >> a away? The field in the aperture is constant, spatially:

 $E_N(x',y',t) = E_{N0}e^{-i\omega t} \quad ,$

and the geometry is as follows:

2 April 2004

The circular aperture (continued)

The aperture is symmetrical about the *z* axis, so we expect that the answer will be independent of the "screen" azimuthal coordinate Φ ; without loss of generality, then, we can take $\Phi = 0$. The integral over ϕ' becomes

$$\mathcal{J} = \int_{0}^{2\pi} d\phi' \exp\left(-\frac{ikr'q}{r}\cos\phi'\right)$$

Don't try to integrate that directly; it's a Bessel function of the first kind, order zero:

$$J_0(-u) = J_0(u) = \frac{1}{2\pi} \int_0^{2\pi} e^{iu\cos v} dv \quad \Rightarrow \quad \mathcal{J} = 2\pi J_0\left(\frac{kr'q}{r}\right) \quad .$$
2 April 2004 Physics 218, Spring 2004 5

Flashback: Bessel functions

The Bessel function of the first kind, of order m, can be represented by the integral

$$J_m(u) = \frac{i^{-m}}{2\pi} \int_0^{2\pi} e^{i(mv + u\cos v)} dv \quad .$$

Bessel functions of different order are related by the recurrence relation

$$\frac{d}{du} \left[u^m J_m(u) \right] = u^m J_{m-1}(u) \iff u^m J_m(u) = \int_0^u v^m J_{m-1}(v) dv$$
Recurrence relations of special functions are very useful when one has to integrate those special functions, as you're about to see.

Poisson's spot

Not all effects named after famous physicists are meant to honor their namesakes.

- □ In 1818, the French Academy, led by neo-Newtonians like Laplace, Biot and Poisson, offered a prize for the best work on the theme of diffraction, expecting that the result would be a definitive refutation of the wave theory of light.
- General Fresnel, supported by Ampère and Arago, offered a paper in which he developed the scalar theory of diffraction in much the same way we did, based on the wave theory.
- During Fresnel's talk, Poisson pointed out that one of the consequences of Fresnel's theory was the intensity peak in the center of circular shadows that we just found. 2 April 2004 19

Physics 218, Spring 2004

Poisson's spot (continued) Deisson did this, of course, because he thought such a result was ridiculous; he meant it as a fatal objection to Fresnel's theory. But right after the talk, Arago went into his lab, observed the intensity peak and concentric rings in the shadow directly, and proceeded to demonstrate it to the judges. □ Thus Fresnel was awarded the prize, the corpuscular theory of light stood

refuted (until Einstein and Planck came along), and the intensity peak has been known ever since as **Poisson's spot**. Physics 218, Spring 2004
