

Radiation - Reaction Force - radiation damping (Griffiths § 22, Feynman v II chpt 28, Jackson chpt 17)

So far, we considered problems of two types:

- 1) Given \mathbf{f} and \mathbf{f}' , find \mathbf{E} and \mathbf{B}
- 2) given \mathbf{E} and \mathbf{B} , find forces on \mathbf{f} and \mathbf{f}' , and compute motion of charges

Now we combine the two ~~two~~ types of problems.

We've seen that charges produce \mathbf{E} and \mathbf{B} fields, and accelerating charges radiate \mathbf{E} and \mathbf{B} fields in the form of electromagnetic waves. These radiated fields can then act back on the charge, and effect the charge's subsequent motion. This force on the charge, due to its own radiated \mathbf{E} and \mathbf{B} fields, is called the "radiation - ~~reaction~~ reaction force". Another way to see that there should be such a force: as a charge accelerates, it radiates away energy in the form of electromagnetic radiation - the resulting loss in energy should be reflected in a ~~decrease~~ ^{increase} in the particle's kinetic energy (via energy conservation) and hence in the particle's velocity - hence the radiation of e-m waves should alter the charge's ~~future~~ future motion.

Thus problems (1) and (2) above, can never really be independent. The motion of charges is coupled back to the fields they produce, which in turn are determined by the charges motion! ~~The~~ The self-consistent solution to this coupled problem

causes conceptual difficulties which have never been satisfactorily resolved ~~so~~ to this day. We will see however that these ~~per~~ difficulties only arise on time and length scales where classical physics breaks down. Unfortunately, quantum mechanics has also not satisfactorily dealt with these difficulties.

To see when the radiation-reaction force will play an important role in the motion of a charged particle, consider following situations:

- D) charge q , initially at rest, is acted on by force for a time T .

The change in kinetic energy after time T is

$$E_0 \sim m(aT)^2 \quad \text{where } a \text{ is the average acceleration due to the force}$$

From Larmor's formula, the power radiated away is $\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2 a^2}{c^3}$. So during the particle's acceleration

$$\text{it loses total energy } E_{\text{rad}} \sim \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2 a^2}{c^3} T.$$

The radiation will play a negligible role in determining the particle's motion (if the radiation-reaction force can be considered as a small perturbation) when $E_{\text{rad}} \ll E_0$. Conversely, radiation plays a major

role in the particles motion when $E_{\text{rad}} \gtrsim E_0$. This is true when

$$\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2 a^2}{c^3} T \gtrsim m(aT)^2$$

$$\text{or when } T \lesssim \tau = \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2}{mc^3}$$

For an electron $q=e$, $m=m_e$ (this gives largest possible τ)

$$\tau \approx 6.26 \times 10^{-24} \text{ sec}$$

(ie dramatically alter motion of charge)

So radiative effects are only important on two scales

$$t \lesssim 6.26 \times 10^{-24} \text{ sec}$$

Q) Consider a charge q undergoing periodic motion with frequency ω_0 , and amplitude of oscillation a .

Typical kinetic energy is

$$E_0 \approx m\omega_0^2 a^2$$

$E_{\text{rad}} \gtrsim E_0$ when

$$\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2 a^2}{c^3} T \approx \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2}{c^3} (\omega_0^2 a)^2 \frac{1}{\omega_0} \gtrsim m\omega_0^2 a^2$$

(where we used $T \approx \frac{1}{\omega_0}$, $a \approx \omega_0^2 d$)

$$\Rightarrow \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2}{c^3} \frac{\omega_0}{m} \gtrsim 1 \quad \text{or when } \omega_0 \gtrsim \frac{1}{\tau}$$

$$\text{where } \tau = \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{q^2}{c^3 m} = 6.26 \times 10^{-24} \text{ sec for electron}$$

radiation-reaction a non-perturbative effect only for frequencies $\omega_0 \gtrsim \frac{1}{\tau}$ | as in (1)

To see how small τ_0 , distance traveled by light in time τ_0

$$CT = 2 \times 10^{-13} \text{ cm} \approx \text{typical nuclear radius of a heavy atom}$$

freq of oscillation where radiation-reaction is

$$\text{non-perturbative} \Rightarrow \omega_0 \approx \frac{e}{\hbar} = 0.16 \times 10^{+24} \text{ sec}^{-1}$$

\Rightarrow freq of X-rays (10^{18} sec^{-1})

\Rightarrow freq of atomic spectra (10^{15} sec^{-1})

From Heisenberg uncertainty principle,

if we localized charge in time to within a certainty τ_0 , we would have uncertainty in energy

of

$$\Delta E \sim \frac{\hbar}{\tau_0} \sim \omega_0 = \frac{6.58 \times 10^{-16} \text{ ev-sec}}{6.26 \times 10^{-24} \text{ sec}}$$

$$= 10^8 \text{ ev} = 100 \text{ Mev} = 200 \times \text{rest mass of electron}$$

\approx pion rest mass - nuclear field quanta

All the above implies that radiation-reaction effects remain small corrections to a charge's motion, except when one gets down to nuclear time and length scales. Therefore in classical problems, it is usually a very good approximation to ignore self-force effects in computing the motion of charges. - radiation-reaction effects can be added as a small perturbation.

radiation-reaction effects are small even on atomic scales

$$(\text{Bohr radius} \approx 5 \times 10^{-8} \text{ cm} \gg CT \approx 10^{-13} \text{ cm})$$

$$(\text{atomic energy} \approx 13.6 \text{ eV} \ll \Delta E = 200 \text{ MeV})$$

• (an atom, with the)

Therefore, consider classical model of electron orbiting the nucleus, as planets orbit the sun. Energy radiated in one period of revolution \ll average electron kinetic energy \Rightarrow loss of radiated energy causes electron to slowly spiral ~~out~~ in towards the nucleus. Let's estimate how long it takes for electron in ground state of hydrogen, ~~to lose all its kinetic energy to radiation, and so~~ to spiral into nucleus.

For no radiation: centripetal acceleration is $\vec{a} = -\frac{v^2}{r}\hat{r}$

~~force is $\frac{-1}{4\pi\epsilon_0} \frac{e^2}{r^2} \hat{r}$~~

~~Newton's eqn $\Rightarrow \frac{1}{4\pi\epsilon_0} \frac{e^2}{r^2} = \frac{mv^2}{r}$~~

~~$\Rightarrow \frac{1}{2}mv^2 = \frac{e^2}{4\pi\epsilon_0 \cdot 2r}$~~

kinetic energy in orbit of radius r

energy in orbit of radius r is

$$\frac{1}{2}mv^2 + \underbrace{\frac{-1}{4\pi\epsilon_0} \frac{e^2}{r}}_{\text{potential}} = -\frac{1}{4\pi\epsilon_0} \frac{e^2}{2r}$$

freq of oscillation

$$\omega_0 = \frac{v}{r} = \sqrt{\frac{e^2}{4\pi\epsilon_0 mr^3}}$$

For an electron $-e$ in classical orbit around nucleus of charge $+e$

$$\vec{F} = m\vec{a} \Rightarrow \frac{1}{4\pi\epsilon_0} \frac{e^2}{r^2} = \frac{m v^2}{r} \Rightarrow \frac{1}{2} m v^2 = \frac{1}{4\pi\epsilon_0} \frac{e^2}{2r}$$

Total energy of charge in orbit at radius r is

$$E(r) = \frac{1}{2} m v^2 + V(r) = \frac{1}{4\pi\epsilon_0} \frac{e^2}{2r} - \frac{1}{4\pi\epsilon_0} \frac{e^2}{r} = -\frac{1}{4\pi\epsilon_0} \frac{e^2}{2r}$$

kinetic potential

Now consider the energy lost due to radiation. From Larmor

$$\frac{dE}{dt} = -P = -\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{e^2}{c^3} a^2 \quad \text{use } a = \frac{v^2}{r} = \frac{1}{4\pi\epsilon_0} \frac{e^2}{r^2 m}$$

$$= -\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{e^2}{c^3} \left(\frac{1}{4\pi\epsilon_0} \frac{e^2}{r^2} \frac{1}{m} \right)^2$$

Also

$$\frac{dE}{dt} = \frac{dE}{dr} \frac{dr}{dt} = \frac{d}{dr} \left(-\frac{1}{4\pi\epsilon_0} \frac{e^2}{2r} \right) \frac{dr}{dt} = \frac{1}{4\pi\epsilon_0} \frac{e^2}{2r^2} \frac{dr}{dt}$$

$$\Rightarrow \frac{1}{4\pi\epsilon_0} \frac{e^2}{2r^2} \frac{dr}{dt} = -\frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{e^2}{c^3} \left(\frac{1}{4\pi\epsilon_0} \frac{e^2}{r^2} \frac{1}{m} \right)^2$$

$$\frac{dr}{dt} = -\frac{4}{3} \frac{1}{c^3} \left(\frac{1}{4\pi\epsilon_0} \frac{e^2}{m} \right)^2 \frac{1}{r^2}$$

$$\text{use } \tau = \frac{1}{4\pi\epsilon_0} \frac{2}{3} \frac{e^2}{mc^3}$$

$$\frac{dr}{dt} = -\frac{4}{3} \frac{1}{c^3} \left(\frac{3}{2} c^3 \tau \right)^2 \frac{1}{r^2} = -\frac{3c^3 \tau^2}{r^2}$$

$$\frac{dr}{dt} = -\frac{3c^3 \tau^2}{r^2}$$

determines how radius of orbit decreases in time as energy gets radiated away!

~~$$\text{use } \frac{d^2r}{dt^2} = -\frac{4\pi G e^2}{4\pi G e m r^2}$$~~

~~$$\frac{dr}{dt} = -\frac{4}{3c} \left(\frac{e^2}{4\pi G e m r^2} \right)^{1/2}$$~~

~~$$c = \frac{e^2}{4\pi G m c^3}$$~~

$$\boxed{\frac{dr}{dt} = -\frac{3c^3 \tau^2}{r^2}}$$

= equation of motion for radius of orbit

integrate to get solution

$$\int_{r_0}^{r(t)} dr r^2 = - \int_0^t dt 3c^3 \tau^2$$

$$\frac{r^3(t) - r_0^3}{3} = -3c^3 \tau^2 t$$

$$\boxed{r^3(t) = r_0^3 - 9c^3 \tau^2 t}$$

r^3 decreases linearly in time

above result is only good as long as $r(t) \gtrsim cc$.

But cc is the nuclear size. So we can use above equation for decay of electrons orbit, all the way until the electron crashes into the nucleus!

electron crosses into nucleus when

$$r^3/t \approx 0 = r_0^3 - 9c^3 t^2 t$$

this happens in a time

$$t = \frac{r_0^3}{9c^3 t^2} = \frac{\cancel{r_0^3}}{\cancel{9c^3} \cancel{t^2}} = \left(\frac{r_0}{cc}\right)^3 \frac{t}{9}$$

use Bohr radius for $r_0 = 5 \times 10^{-8}$ cm

$$cc = 2 \times 10^{-13}$$
 cm

$$t = 6 \times 10^{-24}$$
 sec

$$t = \left(\frac{5 \times 10^{-8}}{2 \times 10^{-13}}\right)^3 \frac{6 \times 10^{-24}}{9} = \left(\frac{1}{4}\right)^3 \times 10^{15} \times \frac{6 \times 10^{-24}}{9}$$

$$t \approx 10^{-11} \text{ sec}$$

So if classical mechanics + E+M held on atomic scale,
the lifetime of the hydrogen atom would be 10^{-11} sec.

The experimentally observed stability of the hydrogen atom, as well as the exptly observed absence of radiation from hydrogen in its ground state, were some of the motivating facts that lead to the discovery of quantum mechanics!

Potentials from a moving point charge

Liénard - Wiechert potentials

In general

$$V(\vec{r}, t) = \frac{1}{4\pi\epsilon_0} \int d^3 r' \int dt' \frac{\rho(\vec{r}', t')}{|\vec{r} - \vec{r}'|} \delta(t - t' - \frac{|\vec{r} - \vec{r}'|}{c})$$

$$\vec{A}(\vec{r}, t) = \frac{\mu_0}{4\pi} \int d^3 r' \int dt' \frac{\vec{j}(\vec{r}', t')}{|\vec{r} - \vec{r}'|} \delta(t - t' - \frac{|\vec{r} - \vec{r}'|}{c})$$

For a pt charge moving on trajectory $\vec{r}_0(t)$ with velocity $\vec{v}(t) = \frac{d\vec{r}_0}{dt}$

$$\rho(\vec{r}, t) = q \delta(\vec{r} - \vec{r}_0(t))$$

$$\vec{j}(\vec{r}, t) = q \vec{v}(t) \delta(\vec{r} - \vec{r}_0(t))$$

Substitute in

$$V(\vec{r}, t) = \frac{1}{4\pi\epsilon_0} \int d^3 r' \int dt' \frac{q \delta(\vec{r}' - \vec{r}_0(t'))}{|\vec{r} - \vec{r}'|} \delta(t - t' - \frac{|\vec{r} - \vec{r}'|}{c})$$

do $\int d^3 r'$ using $\delta(\vec{r}' - \vec{r}_0(t'))$ ten

$$= \frac{1}{4\pi\epsilon_0} \int dt' \frac{q}{|\vec{r} - \vec{r}_0(t')|} \delta(t - t' - \frac{|\vec{r} - \vec{r}_0(t')|}{c})$$

now we want to do $\int dt'$ using the $\delta(t - t' - \frac{|\vec{r} - \vec{r}_0(t')|}{c})$

the δ -function is of the form $\delta(g(t'))$ where

$$g(t') = t' - t + \frac{|\vec{r} - \vec{r}_0(t')|}{c}$$

to evaluate, change variable of integration from t' to g

$$\int_{-\infty}^{\infty} dt' f(t') \delta(g(t')) = \int_{g(-\infty)}^{g(\infty)} f(t') \delta(g) \left(\frac{dt'}{dg} \right) dg$$

$$= f(t') \frac{dt'}{dg} = \frac{\delta(t')}{\left(\frac{dg}{dt'} \right)} \quad \text{evaluated at } t' \text{ such that } g(t') = 0$$

Here: $f(t') = \frac{f}{|\vec{r} - \vec{r}_0(t')|}$

$t' = t - \frac{|\vec{r} - \vec{r}_0(t')|}{c}$ is the retarded time

$$\frac{dg}{dt'} = 1 + \frac{1}{c} \frac{d}{dt'} |\vec{r} - \vec{r}_0(t')|$$

$$\frac{d}{dt} \sqrt{(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2} = \frac{-[(x-x_0) \frac{dx_0}{dt} + (y-y_0) \frac{dy_0}{dt} + (z-z_0) \frac{dz_0}{dt}]}{\sqrt{(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2}}$$

$$= -(\vec{r} - \vec{r}_0(t')) \cdot \vec{v}(t')$$

$$|\vec{r} - \vec{r}_0(t')| \quad \text{where } \hat{n}(t') = \frac{\vec{r} - \vec{r}_0(t')}{|\vec{r} - \vec{r}_0(t')|}$$

unit vector from charges position,
at retarded time t' , to observer
at position r , time t .

$$V(\vec{r}, t) = \frac{q}{4\pi\epsilon_0 |\vec{r} - \vec{r}_0(t')|} \frac{1}{1 - \frac{1}{c} \hat{m}(t') \cdot \vec{v}(t')}$$

Liénard-Wiechert potentials

similarly:

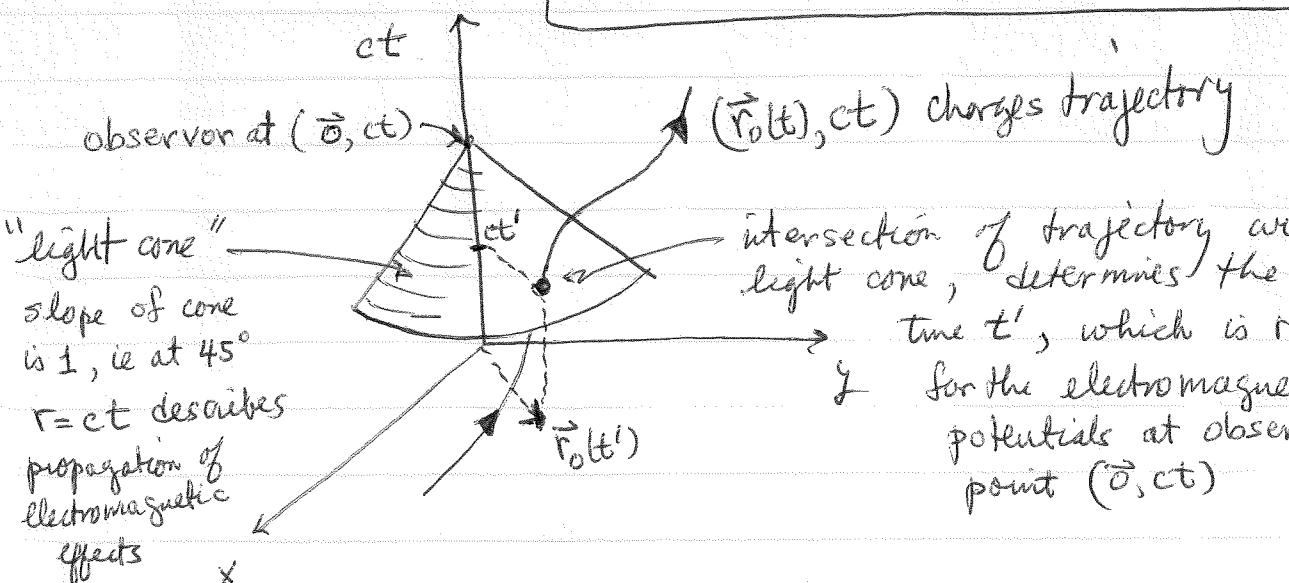

$$\vec{A}(\vec{r}, t) = \frac{\mu_0}{4\pi} \frac{q \vec{v}(t')}{|\vec{r} - \vec{r}_0(t')|} \frac{1}{1 - \frac{1}{c} \hat{m}(t') \cdot \vec{v}(t')}$$

$$t' = t - \frac{|\vec{r} - \vec{r}_0(t')|}{c}$$

$$\text{using } \mu_0 = \frac{1}{\epsilon_0 c^2} \Rightarrow$$

$$\vec{A}(\vec{r}, t) = \frac{\vec{v}(t')}{c^2} V(\vec{r}, t)$$

graphically:

what is observed at the apex of the cone, at point $(\vec{0}, ct)$ can only be caused by events which occurred somewhere on the surface of the light cone.

pts r' on light cone determined by eqn $ct' = ct - r'$ as observer
 $\Rightarrow r' = ct - ct'$ at $\vec{r} = 0$

points inside the light cone arrive at the observer at times earlier than points outside the light cone arrive at the observer at times later than
