

Consider a non-interacting two particle system

Compute  $\langle \vec{r}_1 \vec{r}_2 | \hat{f} | \vec{r}_1 \vec{r}_2 \rangle$  diagonal elements of  $\hat{f}$  in position basis  
 = probability one particle is at  $\vec{r}_1$  and the other is at  $\vec{r}_2$

For free noninteracting particles, the energy eigenstates are specified by two wave vectors  $\vec{k}_1, \vec{k}_2$  with  $E = \frac{\hbar^2}{2m}(k_1^2 + k_2^2)$

The eigenstates are symmetrized plane waves

$$\langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle = \frac{e^{i(\vec{k}_1 \cdot \vec{r}_1 + \vec{k}_2 \cdot \vec{r}_2)} \pm e^{i(\vec{k}_1 \cdot \vec{r}_2 + \vec{k}_2 \cdot \vec{r}_1)}}{\sqrt{2!} (\sqrt{V})^2}$$

$$\begin{aligned} \langle \vec{r}_1 \vec{r}_2 | \hat{f} | \vec{r}_1 \vec{r}_2 \rangle &= \langle \vec{r}_1 \vec{r}_2 | \frac{e^{-\beta \hat{H}}}{Q_2} | \vec{r}_1 \vec{r}_2 \rangle \\ &= \sum_{|\vec{k}_1 \vec{k}_2\rangle} \langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle \frac{e^{-\frac{\beta \hbar^2}{2m}(k_1^2 + k_2^2)}}{Q_2} \langle \vec{k}_1 \vec{k}_2 | \vec{r}_1 \vec{r}_2 \rangle \\ &= \frac{1}{Q_2} \sum_{|\vec{k}_1 \vec{k}_2\rangle} e^{-\frac{\beta \hbar^2}{2m}(k_1^2 + k_2^2)} |\langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle|^2 \end{aligned}$$

Note, if we take  $\vec{k}_1 \rightarrow \vec{k}_2$  and  $\vec{k}_2 \rightarrow \vec{k}_1$ , then  $\langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle = \pm \langle \vec{r}_1 \vec{r}_2 | \vec{k}_2 \vec{k}_1 \rangle$ . Since this matrix element is squared in the above sum, any sign change is canceled out. Thus in taking the sum over all eigenstates, we can replace  $\sum$  by independent sums on  $\vec{k}_1$  and  $\vec{k}_2$  provided we multiply by  $\frac{1}{2!} \sum_{|\vec{k}_1 \vec{k}_2\rangle}$  so as not to double count  $(\vec{k}_1 \vec{k}_2)$  and  $(\vec{k}_2 \vec{k}_1)$  which represent the same physical state.

$$\langle \vec{r}_1 \vec{r}_2 | \hat{e}^{-\beta \hat{H}} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2!} \sum_{|\vec{k}_1 \vec{k}_2\rangle} e^{-\frac{\beta \hbar^2}{2m}(k_1^2 + k_2^2)} |\langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle|^2$$

$$|\langle \vec{r}_1 \vec{r}_2 | \vec{k}_1 \vec{k}_2 \rangle|^2 = \frac{2 \pm e^{i\vec{k}_1 \cdot \vec{r}_{12}} e^{-i\vec{k}_2 \cdot \vec{r}_{12}} + e^{-i\vec{k}_1 \cdot \vec{r}_{12}} e^{i\vec{k}_2 \cdot \vec{r}_{12}}}{2V^2}$$

where  $\vec{r}_{12} = \vec{r}_1 - \vec{r}_2$

$$= \frac{1 \pm \operatorname{Re}[e^{i\vec{k}_1 \cdot \vec{r}_{12}} e^{-i\vec{k}_2 \cdot \vec{r}_{12}}]}{V^2}$$

$$\text{let } \alpha = \frac{\beta \hbar^2}{m}$$

$$\langle \vec{r}_1 \vec{r}_2 | e^{-\beta A} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2! V^2} \sum_{\vec{k}_1 \vec{k}_2} e^{-\frac{\alpha k_1^2}{2}} e^{-\frac{\alpha k_2^2}{2}} (1 \pm \operatorname{Re}[e^{i\vec{k}_1 \cdot \vec{r}_{12}} e^{-i\vec{k}_2 \cdot \vec{r}_{12}}])$$

$$\text{for large } V, \quad \frac{1}{V} \sum_{\vec{k}} = \int \frac{d^3 k}{(2\pi)^3}$$

$$\langle \vec{r}_1 \vec{r}_2 | e^{-\beta A} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2(2\pi)^6} \int d^3 k_1 \int d^3 k_2 e^{-\frac{\alpha k_1^2}{2}} e^{-\frac{\alpha k_2^2}{2}} (1 \pm \operatorname{Re}[e^{i\vec{k}_1 \cdot \vec{r}_{12}} e^{-i\vec{k}_2 \cdot \vec{r}_{12}}])$$

We need the following integral

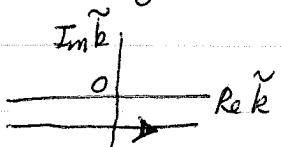

$$\int d^3 k e^{-\frac{\alpha}{2} k^2} = \left(\frac{2\pi}{\alpha}\right)^{3/2}$$

$$\int d^3 k e^{-\frac{\alpha}{2} k^2 + i\vec{k} \cdot \vec{r}} \quad \text{do by "completing the square"}$$

$$-\frac{\alpha}{2} k^2 + i\vec{k} \cdot \vec{r} = -\frac{\alpha}{2} \left(k^2 - \frac{2i\vec{k} \cdot \vec{r}}{\alpha}\right) = -\frac{\alpha}{2} \left[\left(\vec{k} - \frac{i\vec{r}}{\alpha}\right)^2 + \frac{r^2}{\alpha^2}\right]$$

$$= -\frac{\alpha}{2} \vec{k}^2 - \frac{r^2}{2\alpha} \quad \text{where } \vec{\tilde{k}} = \vec{k} - \frac{i\vec{r}}{\alpha}$$

$$\text{So } \int d^3 k e^{-\frac{\alpha}{2} k^2 + i\vec{k} \cdot \vec{r}} = \int d^3 \vec{\tilde{k}} e^{-\frac{\alpha}{2} \vec{\tilde{k}}^2} e^{-r^2/2\alpha}$$

$$= \left(\frac{2\pi}{\alpha}\right)^{3/2} e^{-r^2/2\alpha}$$

Contour of integration over  $\vec{k}$  can be moved back to real axis as it encloses no poles

as it encloses no poles

$$\text{So } \langle \vec{r}_1 \vec{r}_2 | e^{-\beta \hat{H}} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2(2\pi)^6} \left( \frac{2\pi}{\alpha} \right)^3 \left[ 1 \pm e^{-r_{12}^2/\alpha} \right]$$

$$= \frac{1}{2(2\pi\alpha)^3} \left[ 1 \pm e^{-r_{12}^2/\alpha} \right]$$

It is customary to introduce the thermal wavelength  $\lambda$  by

$$\lambda^2 = \frac{2\pi\alpha}{2\pi\beta} = \frac{2\pi\beta\hbar^2}{m} = \frac{2\pi\hbar^2}{k_B T m} \equiv \frac{\hbar^2}{2\pi m k_B T}$$

Then

$$\langle \vec{r}_1 \vec{r}_2 | e^{-\beta \hat{H}} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2\lambda^6} \left[ 1 \pm e^{-2\pi r_{12}^2/\lambda^2} \right]$$

Now we need

$$\begin{aligned} Q_2 &= \int d^3r_1 \int d^3r_2 \langle \vec{r}_1 \vec{r}_2 | e^{-\beta \hat{H}} | \vec{r}_1 \vec{r}_2 \rangle \\ &= \frac{1}{2\lambda^6} \int d^3r_1 \int d^3r_2 \left[ 1 \pm e^{-2\pi r_{12}^2/\lambda^2} \right] \\ &\quad \text{let } \vec{R} = \frac{\vec{r}_1 + \vec{r}_2}{2}, \vec{r} = \vec{r}_1 - \vec{r}_2 = \vec{r}_{12} \\ &= \frac{1}{2\lambda^6} \int d^3R \int d^3r \left[ 1 \pm e^{-2\pi r^2/\lambda^2} \right] \\ &= \frac{V}{2\lambda^6} \left[ V \pm \int_0^\infty dr 4\pi r^2 e^{-2\pi r^2/\lambda^2} \right] \\ &= \frac{1}{2} \left( \frac{V}{\lambda^3} \right)^2 \left[ 1 \pm \frac{1}{2^{3/2}} \left( \frac{2\beta}{V} \right) \right] \\ &\approx \frac{1}{2} \left( \frac{V}{\lambda^3} \right)^2 \quad \text{as } V \rightarrow \infty \end{aligned}$$

$$\text{So } \langle \vec{r}_1 \vec{r}_2 | \hat{f} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{2\lambda^6} \left[ 1 \pm e^{-2\pi r_{12}^2/\lambda^2} \right]$$

$\langle \vec{r}_1 \vec{r}_2   \hat{f}   \vec{r}_1 \vec{r}_2 \rangle$	$= \frac{1}{V^2} \left[ 1 \pm e^{-2\pi r_{12}^2/\lambda^2} \right]$
---	---

= probability one particle is at  $\vec{r}_1$  and the other is at  $\vec{r}_2$

Consider two classical non-interacting particles. Since the positions of these particles are uncorrelated, we have

$$\langle \vec{r}_1 \vec{r}_2 | \hat{f} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{V^2}$$

The  $\pm e^{-2\pi r_{12}^2/\lambda^2}$  terms are therefore the spatial correlations introduced into the pair probability due to the quantum statistics (FBE, or -FD)

we can treat this quantum correlation as an effective classical interaction between the two particles. For classical particles with a pair wise interaction  $V(\vec{r}_1 - \vec{r}_2)$ , the classical prob to have one particle at  $\vec{r}_1$  and the second at  $\vec{r}_2$  is

$$P(\vec{r}_1 \vec{r}_2) = \frac{\sum_{P_1 P_2} e^{-\beta \left[ \frac{P_1^2}{2m} + \frac{P_2^2}{2m} + V(r_{12}) \right]}}{\sum_{P_1 P_2} \sum_{r_1 r_2} e^{-\beta \left[ \frac{P_1^2}{2m} + \frac{P_2^2}{2m} + V(r_{12}) \right]}}$$

$$= \frac{e^{-\beta V(r_{12})}}{\sum_{r_1 r_2} e^{-\beta V(r_{12})}}$$

For large  $V$ , and assuming  $v(r_{12}) \rightarrow 0$  as  $r_{12} \rightarrow \infty$

$$\phi(\vec{r}_1 \vec{r}_2) = \frac{e^{-\beta U(r_{12})}}{V^2}$$

Compare with our expressions from quantum statistics

$$\langle \vec{r}_1 \vec{r}_2 | \hat{f} | \vec{r}_1 \vec{r}_2 \rangle = \frac{1}{r^2} \left[ 1 \pm e^{-2\pi r_{12}^2/\lambda^2} \right]$$

$$\Rightarrow v_{\pm}(r) = -k_B T \ln \left[ 1 \pm e^{-2\pi r^2/\lambda^2} \right]$$

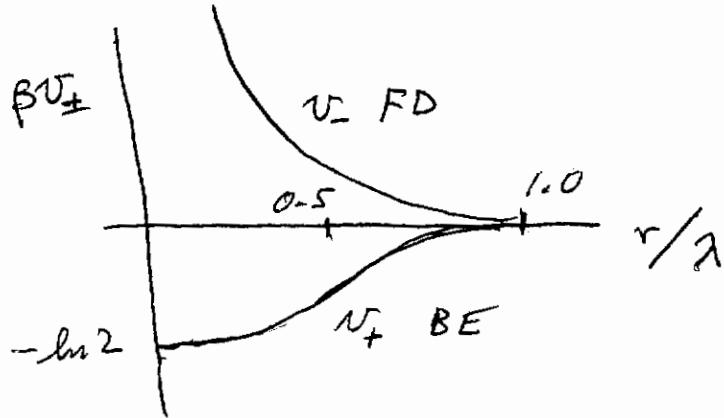

$$\frac{\hbar}{2\pi} = \frac{k}{\lambda}$$

+ for BE, - for FD

$$\lambda^2 = \frac{2\pi\beta\hbar^2}{m} = \frac{2\pi\hbar^2}{m k_B T} = \frac{\hbar^2}{2\pi m k_B T}$$

we can plot these as

Pathria Fig 5.1

we see that the BE statistics lead to an effective attraction while FD statistics lead to an effective repulsion, for small separations

$$r \lesssim \lambda$$

## N-particles

$$\text{eigenstates } \langle \vec{r}_1 \dots \vec{r}_N | \vec{k}_1 \dots \vec{k}_N \rangle = \frac{1}{\sqrt{N! V^N}} \sum_{\mathbb{P}} (\pm 1)^{\mathbb{P}} e^{i \sum_i (\mathbb{P} \vec{r}_i) \cdot \vec{k}_i}$$

where  $\mathbb{P} \vec{r}_i$  is the permutation of position  $\vec{r}_i$ .

e.g. if  $\mathbb{P}(123) = 231$  then  $P1=2$ ,  $P2=3$  and  $P3=1$

$$\langle \vec{r}_1 \dots \vec{r}_N | e^{-\beta \hat{H}} | \vec{r}_1 \dots \vec{r}_N \rangle = \sum_{\{k_1 \dots k_N\}} e^{-\frac{\beta \hbar^2}{2m} (k_1^2 + \dots + k_N^2)} |\langle \vec{r}_1 \dots \vec{r}_N | \vec{k}_1 \dots \vec{k}_N \rangle|^2$$

$$|\langle \vec{r}_1 \dots \vec{r}_N | \vec{k}_1 \dots \vec{k}_N \rangle|^2 = \frac{1}{N! V^N} \sum_{\mathbb{P}} \sum_{\mathbb{P}'} (\pm 1)^{\mathbb{P} + \mathbb{P}'} e^{i \sum_i [\mathbb{P} \vec{r}_i - \mathbb{P}' \vec{r}_i] \cdot \vec{k}_i}$$

Note: we can write  $[\mathbb{P} \vec{r}_i - \mathbb{P}' \vec{r}_i] \cdot \vec{k}_i = [\mathbb{P}(\vec{r}_i - \mathbb{P}' \mathbb{P}' \vec{r}_i)] \cdot \vec{k}_i$

where  $\mathbb{P}'$  is inverse permutation of  $\mathbb{P}$

$$\text{and } (\pm 1)^{\mathbb{P}} = (\pm 1)^{\mathbb{P}'}$$

$$= (\vec{r}_i - \mathbb{P}' \mathbb{P}' \vec{r}_i) \cdot \mathbb{P}' \vec{k}_i$$

$$|\langle \vec{r}_1 \dots \vec{r}_N | \vec{k}_1 \dots \vec{k}_N \rangle|^2 = \frac{1}{N! V^N} \sum_{\mathbb{P}} \sum_{\mathbb{P}''} (\pm 1)^{\mathbb{P}''} e^{i \sum_i (\vec{r}_i - \mathbb{P}'' \vec{r}_i) \cdot \mathbb{P}' \vec{k}_i}$$

$$\text{where } \mathbb{P}'' = \mathbb{P}' \mathbb{P}'$$

Now when we sum over the energy eigenstates, we sum over  $\vec{k}_i$ . Since  $\vec{k}_i$  is a dummy index in the sum, it does not matter whether we label it  $\vec{k}_i$  or  $\mathbb{P}' \vec{k}_i$ . So in the above, each term in the  $\sum_{\mathbb{P}}$  contributes an equal amount.

We can therefore replace  $\sum_{\mathbb{P}}$  by  $N!$  times the one term with  $\mathbb{P} = \mathbb{I}$  the identity. Similarly when we do the sum on eigenstates  $\sum_{\{k_1 \dots k_N\}}$  we can do independent sums on  $\vec{k}_1 \dots \vec{k}_N$  provided  $|\vec{k}_1 \dots \vec{k}_N\rangle$  we add a factor  $1/N!$  to prevent double counting.

The result is

$$\begin{aligned} & \langle \vec{r}_1 \dots \vec{r}_N | e^{-\beta \hat{H}} | \vec{r}_1 \dots \vec{r}_N \rangle = \\ & \frac{1}{N! V^N} \sum_{\vec{k}_1 \dots \vec{k}_N} e^{-\frac{\beta \hbar^2}{2m} (\vec{k}_1^2 + \dots + \vec{k}_N^2)} \sum_P (\pm 1)^P e^{i \sum_i \vec{k}_i \cdot (\vec{r}_i - P \vec{r}_i)} \\ & = \frac{1}{N! (2\pi)^{3N}} \sum_P (\pm 1)^P \prod_{i=1}^N \left[ \int d^3 k_i e^{-\frac{\beta \hbar^2}{2m} k_i^2 + i \vec{k}_i \cdot (\vec{r}_i - P \vec{r}_i)} \right] \end{aligned}$$

The integral we did when considering the two body problem.

$$\begin{aligned}
 &= \frac{1}{N! (2\pi)^{3N}} \sum_P (\pm 1)^P \prod_{i=1}^N \left[ \left( \frac{2\pi}{\alpha} \right)^{3/2} e^{-\frac{(\vec{r}_i - P\vec{r}_c)^2}{2\alpha}} \right] \quad \alpha = \frac{\beta \hbar^2}{m} \\
 &= \frac{1}{N! (2\pi)^{3N}} \left( \frac{2\pi}{\alpha} \right)^{3N/2} \sum_P (\pm 1)^P \prod_{i=1}^N f(\vec{r}_i - P\vec{r}_c) \\
 &= \frac{1}{N! \lambda^{3N}} \sum_P (\pm 1)^P \prod_{i=1}^N f(\vec{r}_i - P\vec{r}_c) \quad \text{where } f(r) = e^{-r^2/2\alpha} \\
 &\quad \text{where } \lambda^2 = 2\pi\alpha = \frac{2\pi\beta \hbar^2}{m}
 \end{aligned}$$

## Partition function

$$Q_N = \int d^3r_1 \dots \int d^3r_N \langle \vec{r}_1 \dots \vec{r}_N | e^{-\beta H} | \vec{r}_1 \dots \vec{r}_N \rangle$$

$$= \frac{1}{N! \lambda^{3N}} \sum_P (\pm 1)^P \int d^3r_1 \dots \int d^3r_N f(\vec{r}_1 - P\vec{r}_1) \dots f(\vec{r}_N - P\vec{r}_N)$$

in the  $\sum_P$

leading term is when  $P = I$  the identity. Then  
 $P\vec{r}_i = \vec{r}_i$  and all the  $f$  terms are  $f(0) = 1$

The next ~~successive~~ leading terms are those corresponding to one pair exchange, say  $P\vec{r}_i = \vec{r}_j$  and  $P\vec{r}_j = \vec{r}_i$ , for then only two of the  $f$  factors are not unity. The next order are terms from permutations  $P\vec{r}_i = \vec{r}_j$ ,  $P\vec{r}_j = \vec{r}_k$ ,  $P\vec{r}_k = \vec{r}_i$ , three particle exchanges, etc.

$$Q_N = \frac{V^N}{N! \lambda^{3N}} \left\{ 1 \pm \sum_{i < j} \int \frac{d^3 r_i}{V} \int \frac{d^3 r_j}{V} f(\vec{r}_i - \vec{r}_j) f(\vec{r}_j - \vec{r}_i) \right. \\ \left. + \sum_{i < j < k} \int \frac{d^3 r_i}{V} \int \frac{d^3 r_j}{V} \int \frac{d^3 r_k}{V} f(\vec{r}_i - \vec{r}_j) f(\vec{r}_j - \vec{r}_k) f(\vec{r}_k - \vec{r}_i) \right. \\ \left. \pm \dots \dots \right\}$$

The leading term  $\frac{V^N}{N! \lambda^{3N}}$  is just the classical result,

provided we take the phase space parameter  $\hbar$  to be Planck's constant. We get the Gibbs  $\frac{1}{N!}$  factor automatically. The higher order terms are the quantum corrections arising from 2-particle, 3-particle, etc, exchanges.

For FD, the terms add with alternating signs

For BE, the terms all add with (+) sign.

We are now ready to compute the Partition function,  
 for non-interacting fermions + bosons (ie ideal  
 quantum gas)

$$Q_N(T, \nu) = \sum_{\{n_i\}} e^{-\beta E(\{n_i\})}$$

↑ sum over all  $\{n_i\}$ 's such that  $\sum n_i = N$

$$= \sum_{\{n_i\}} \delta(\sum_i n_i - N) e^{-\beta \sum_i \epsilon_i n_i}$$

↑ sum over all  $\{n_i\}$ 's. constraint now  
 handled by the  $\delta$ -function

$$= \sum_{\{n_i\}} \delta(\sum_i n_i - N) \prod_i e^{-\beta \epsilon_i n_i}$$

Because of the constraint  $\sum_i n_i = N$  it is difficult to  
 carry out the summation.  $\Rightarrow$  go to grand canonical  
 ensemble

$$\mathcal{Z}(T, \nu, z) = \sum_{N=0}^{\infty} z^N Q_N$$

$$z^N = z^{\sum n_i} = \prod_i z^{n_i}$$

$$= \sum_{N=0}^{\infty} \sum_{\{n_i\}} \delta(\sum_i n_i - N) \prod_i z^{n_i} e^{-\beta \epsilon_i n_i}$$

do  $\sum_N$  first to eliminate  $\delta$ -function

$$\mathcal{Z} = \sum_{\{n_i\}} \prod_i (ze^{-\beta \epsilon_i})^{n_i}$$

↑ unconstrained sum over all  
 sets of occupation numbers
